

Load Forecast Model Development

Andrew Gledhill
Resource Adequacy Planning

Load Analysis Subcommittee
October 27, 2022

- After an RFP process, PJM engaged with Itron starting in late April to perform a model review and to make recommendations for potential model enhancements as we transition to an hourly model for the 2023 Load Forecast.
 - Early discussion and feedback session at Load Analysis Subcommittee (LAS) on June 10, 2022
 - Itron presented their review and recommendations, and solicited feedback at LAS on July 28, 2022
 - Itron delivered their final report to PJM consistent with their presentation from July 28, 2022

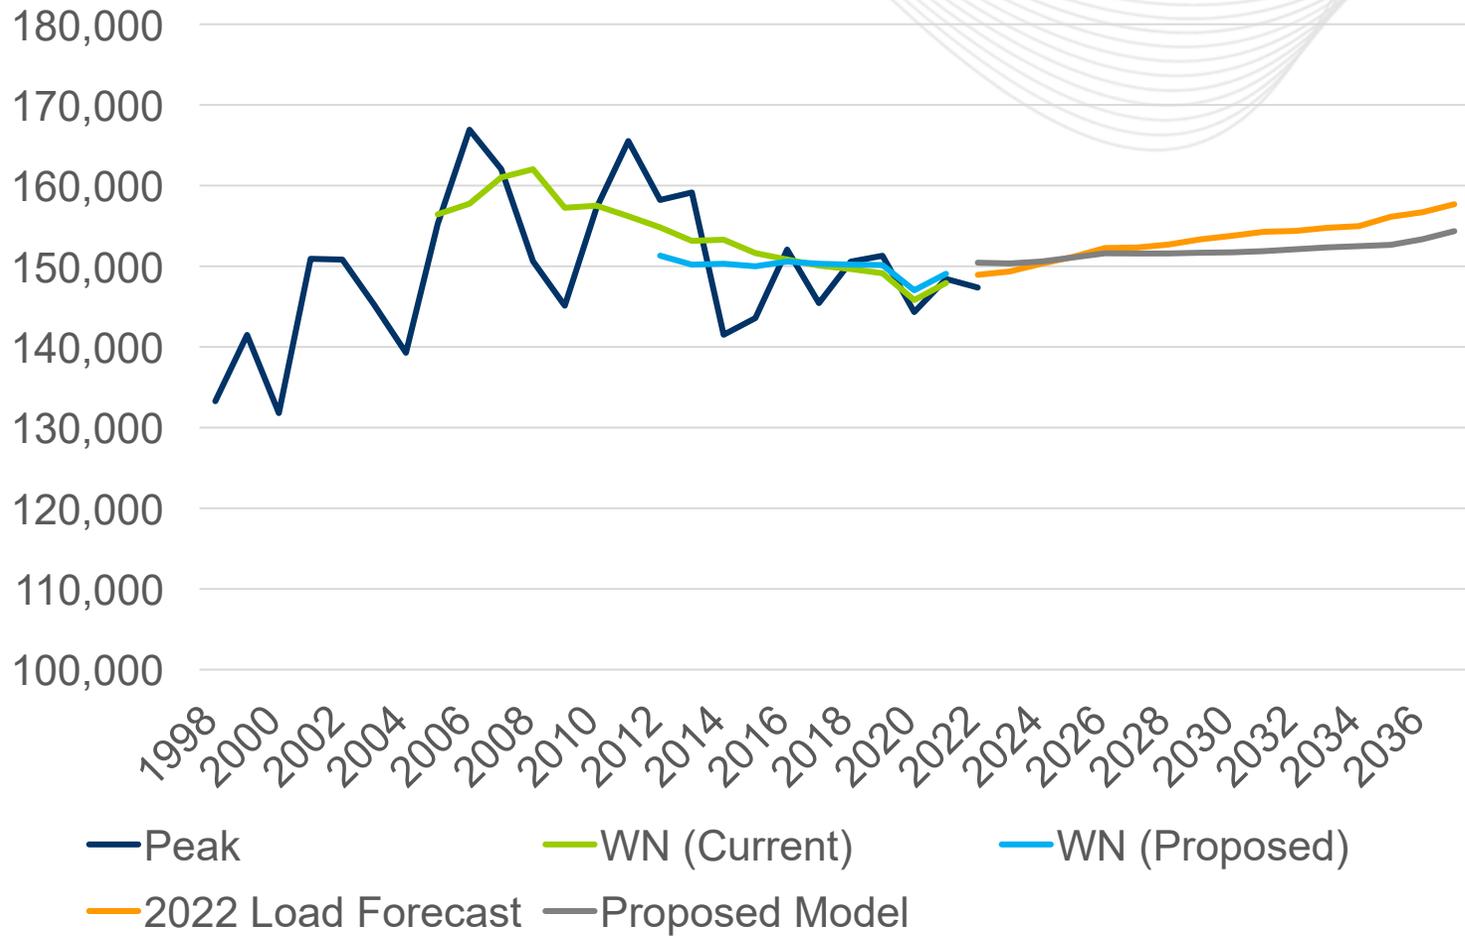

- 1) Replace Annual/Quarterly End-Use Indices with Monthly/Daily Indices
 - a) Discussed method at 9/12 LAS.

- 2) Continue with Weather Simulation Approach
 - a) Discuss results of today.

- 3) Replace Daily Models (Energy, Zone peak, and Coincident peak) with Hourly Load Models
 - a) Discussed at 9/12 LAS. Results to be discussed today.

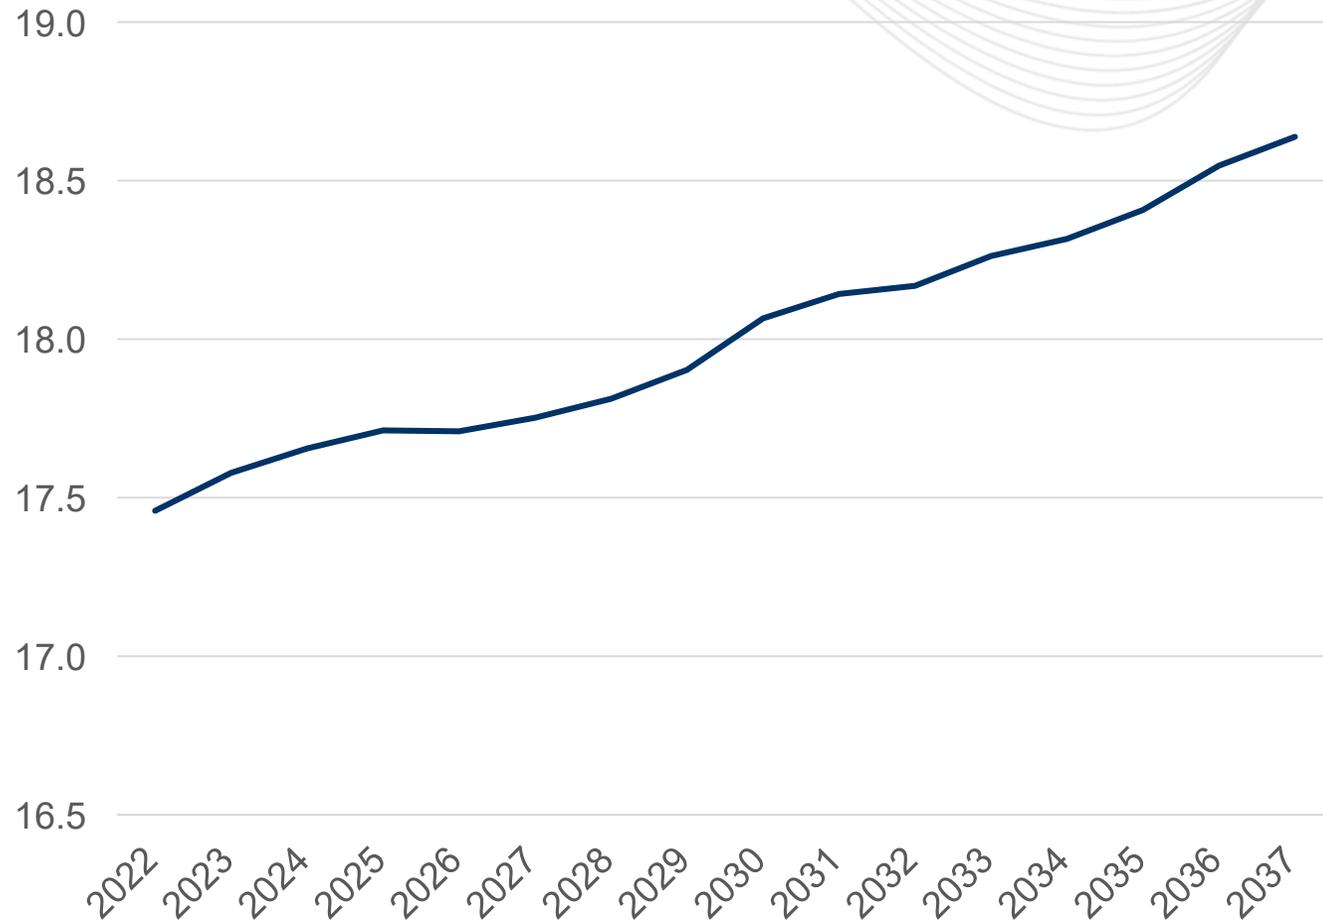

- 4) Adjust Loads for Solar and New Technologies Through the Simulation Process
 - a) Discussed at 9/12 LAS.

- 5) Capture Increasing Temperature Trends
 - a) Discussion deferred to next year.

- Slightly higher starting point
 - 2022 – up 1%
- Slightly slower 15-yr average annual growth rate
 - 0.2% vs 0.4% currently

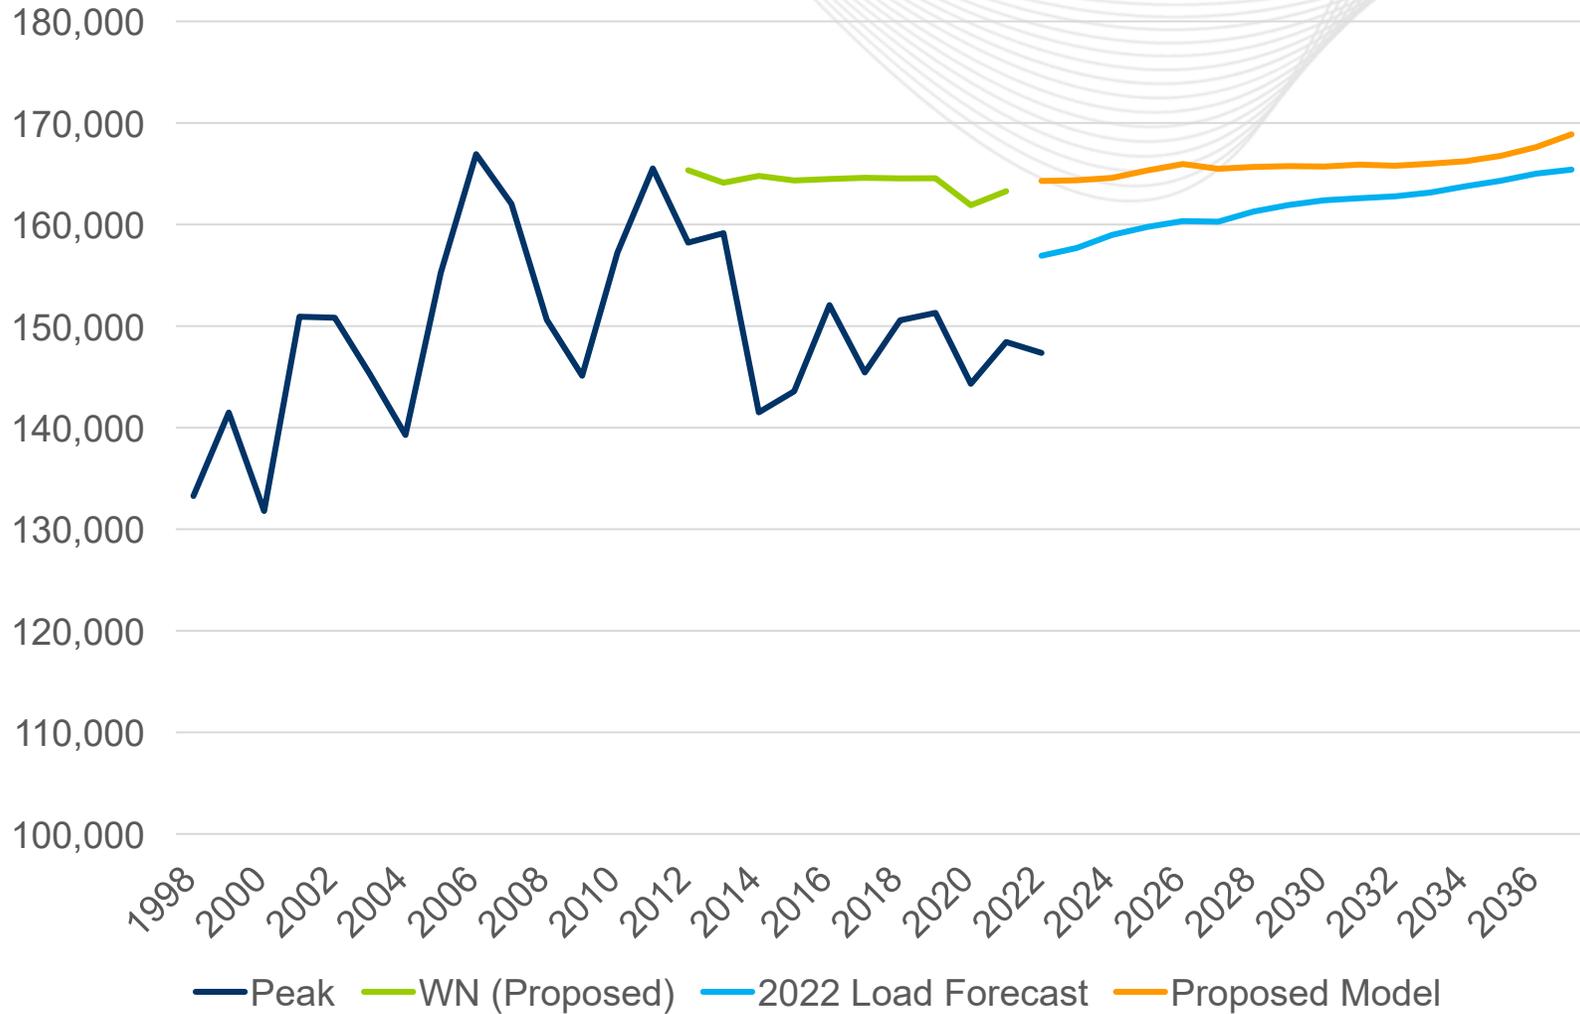

Average Hour of Summer Peak

- Continued penetration of Behind-the-Meter Solar pushes the peak to later hour

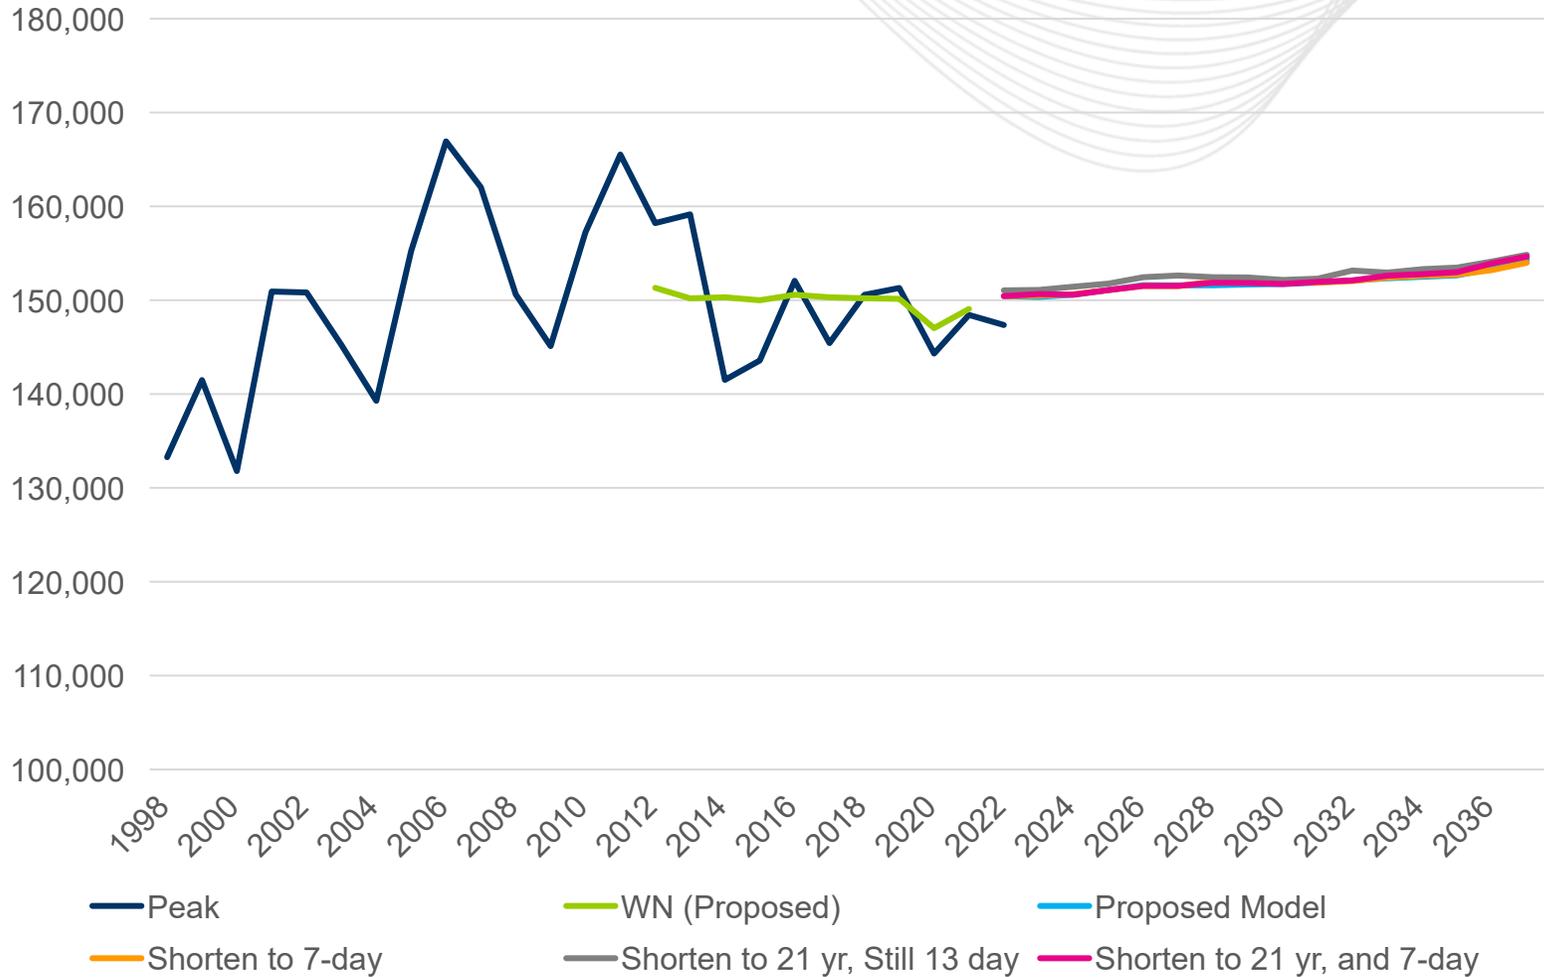

RTO 90/10 Summer Peak Forecast

- Higher level
- Slightly slower 15-yr growth

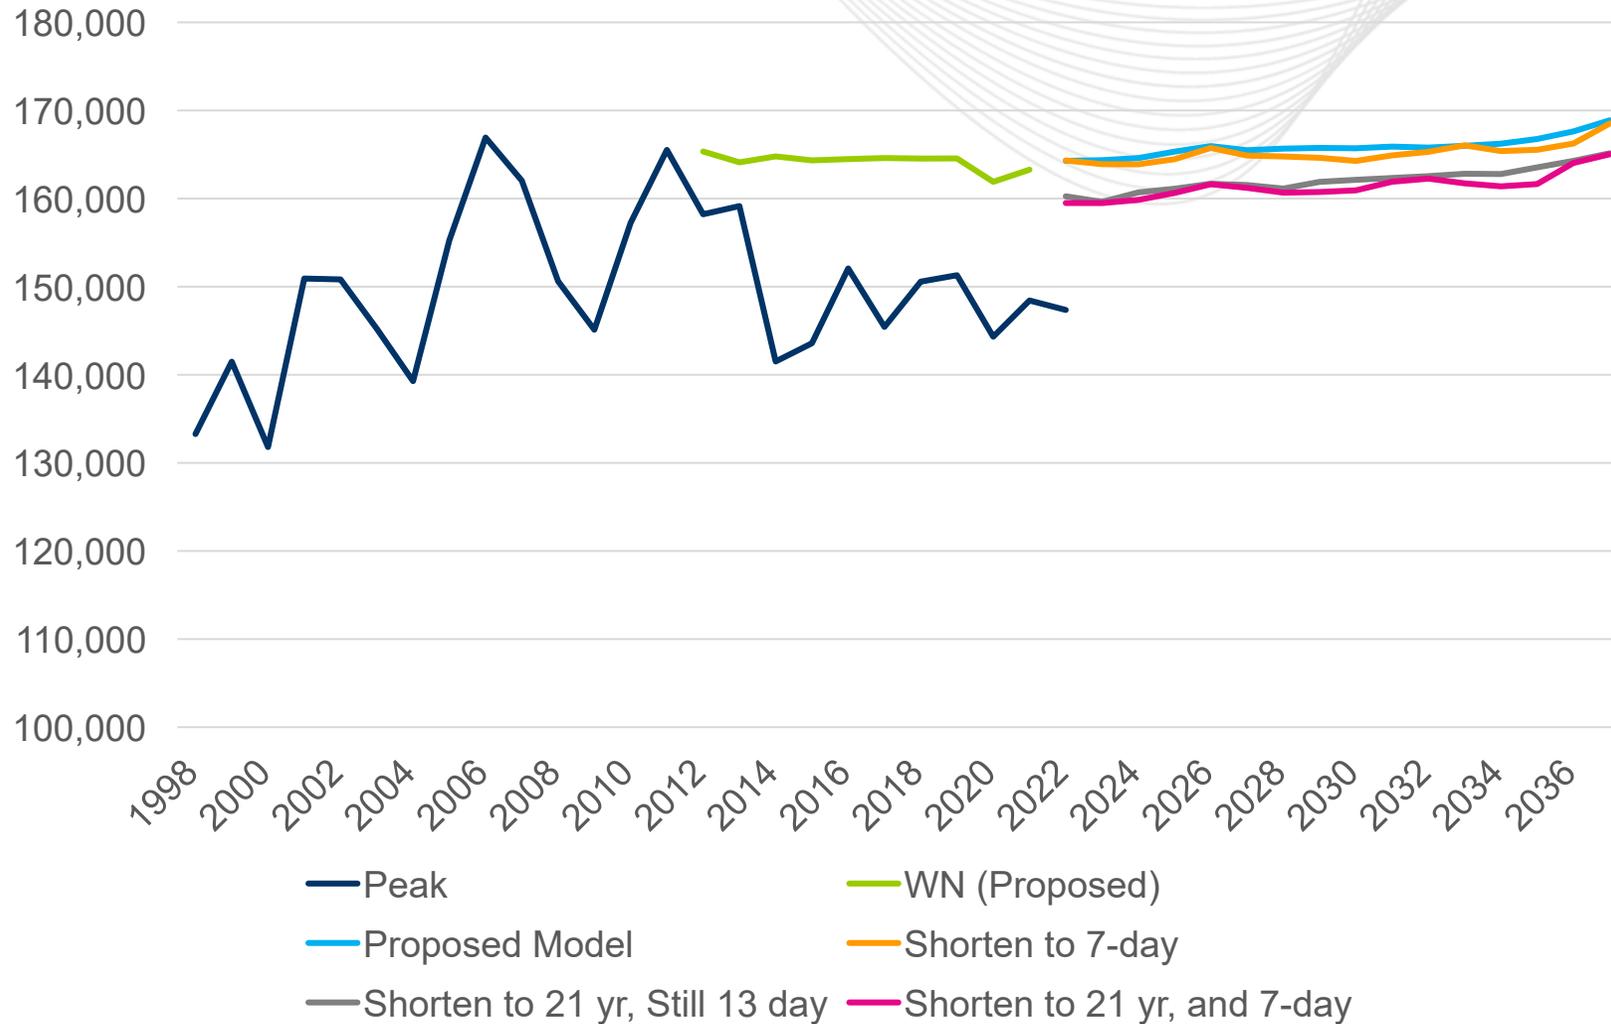

RTO 50/50 Summer Peak Forecast Impact of Weather Simulation Proposal

- No significant impact to 50/50 forecast from changing the weather simulation

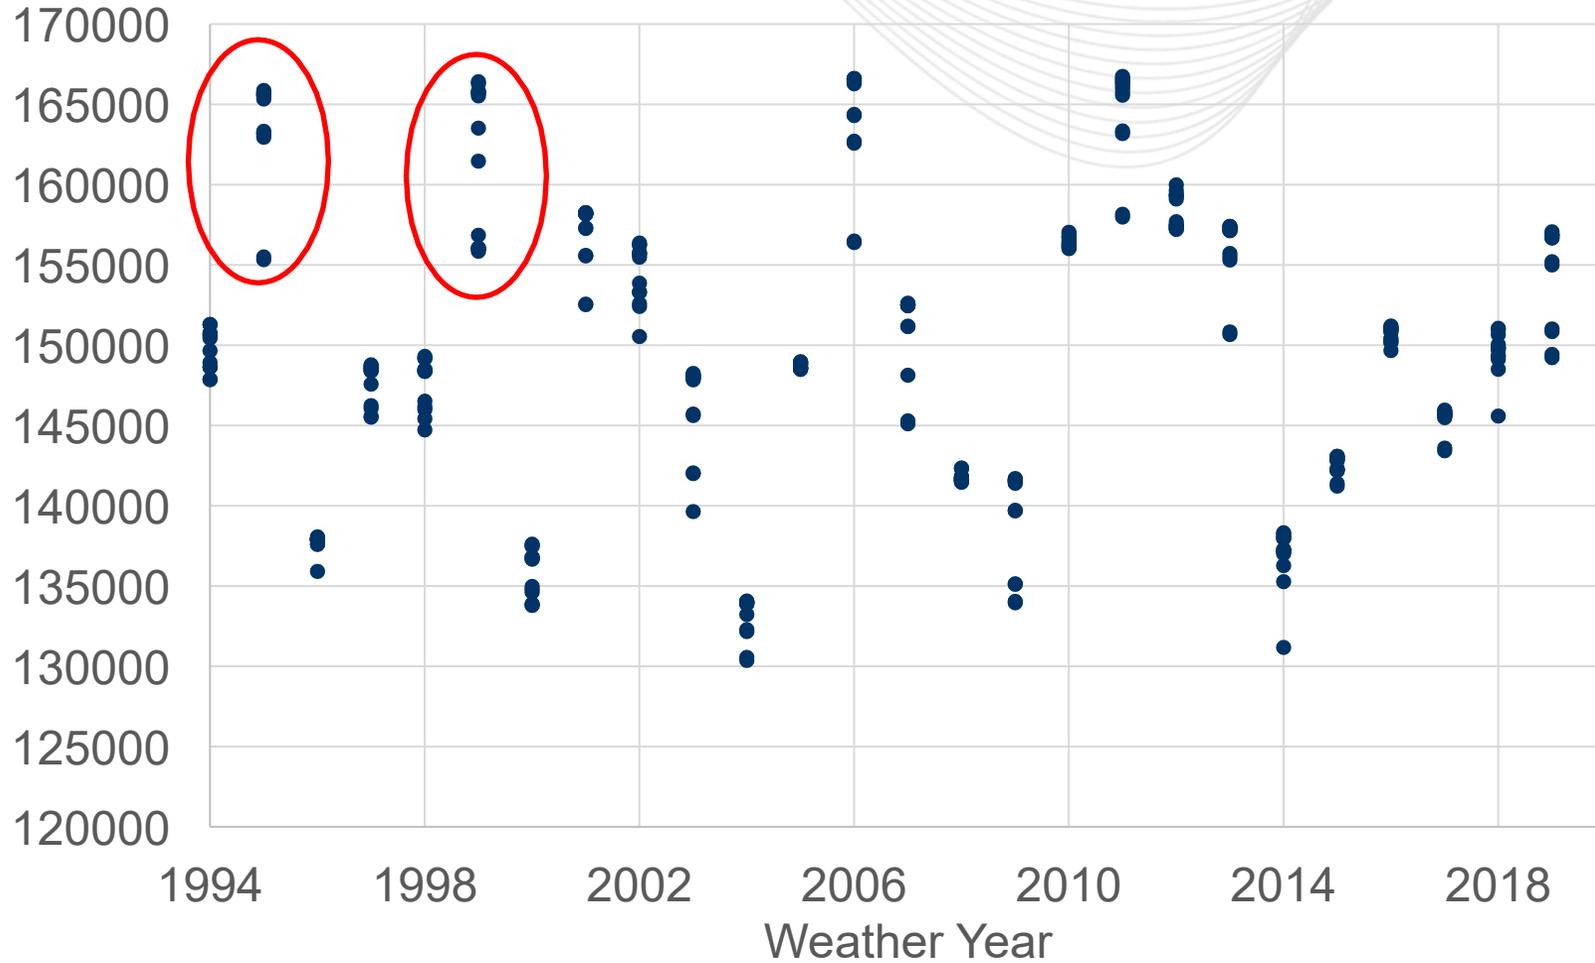

RTO 90/10 Summer Peak Forecast Impact of Weather Simulation Proposal

- Extreme values are lower with shortened weather simulation

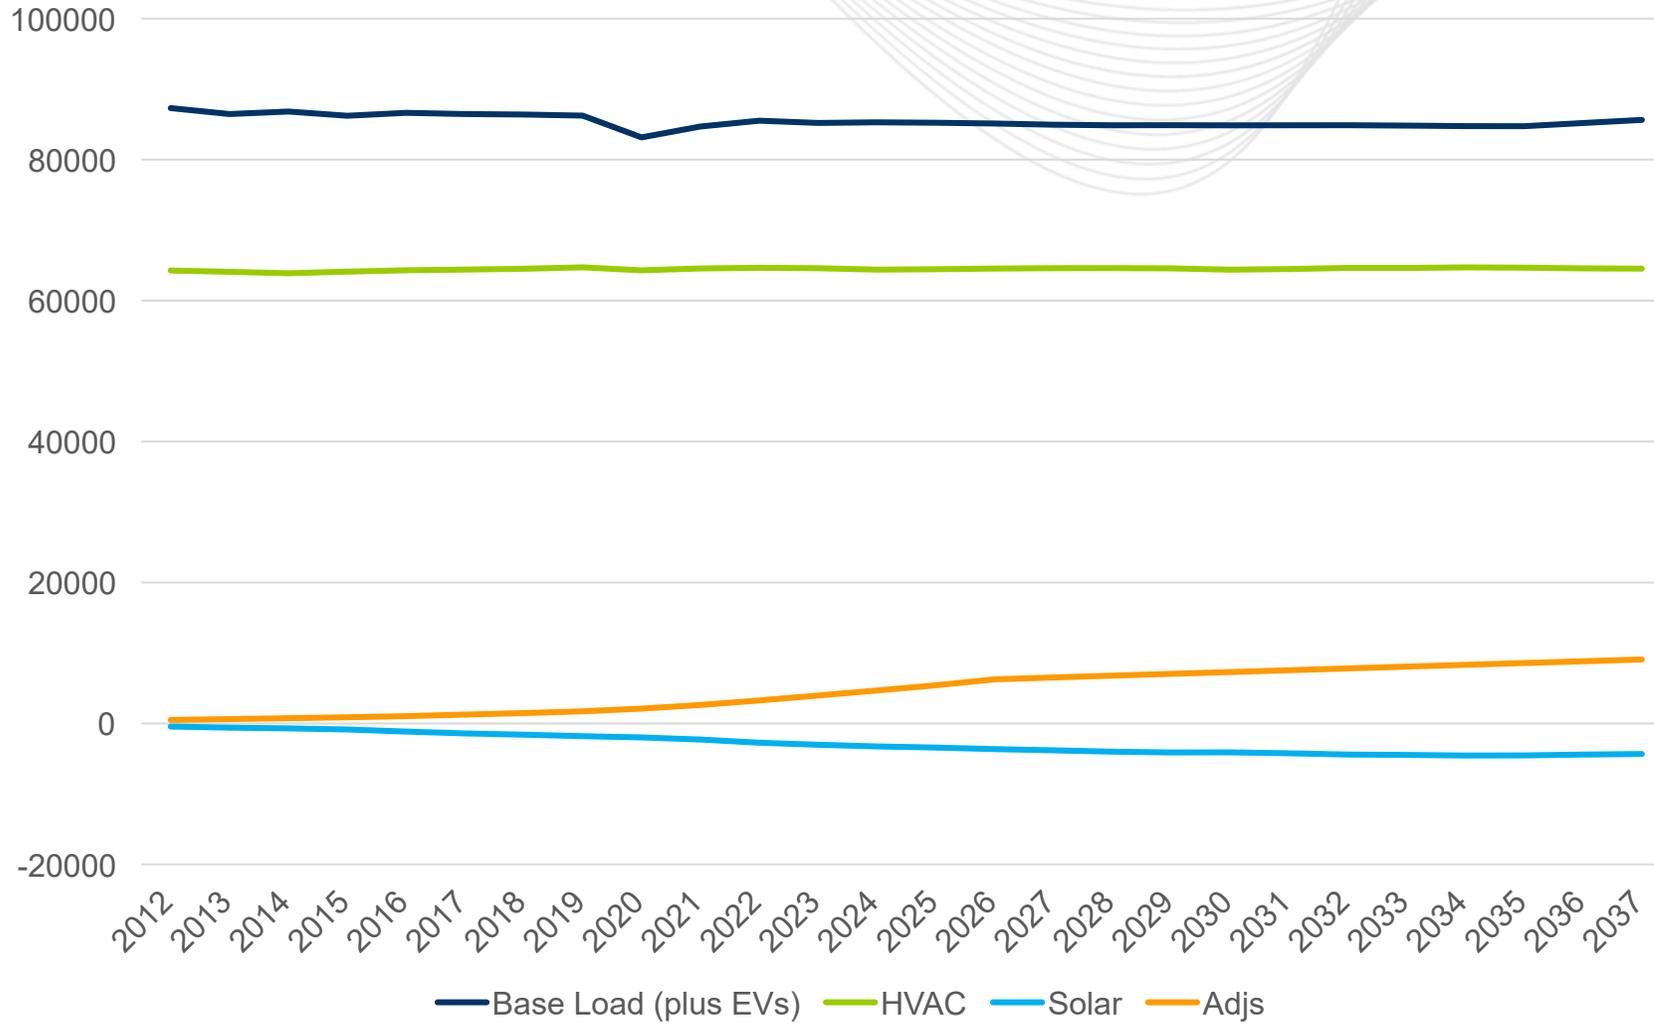

2022 Summer Coincident Peak Distribution by Weather Year

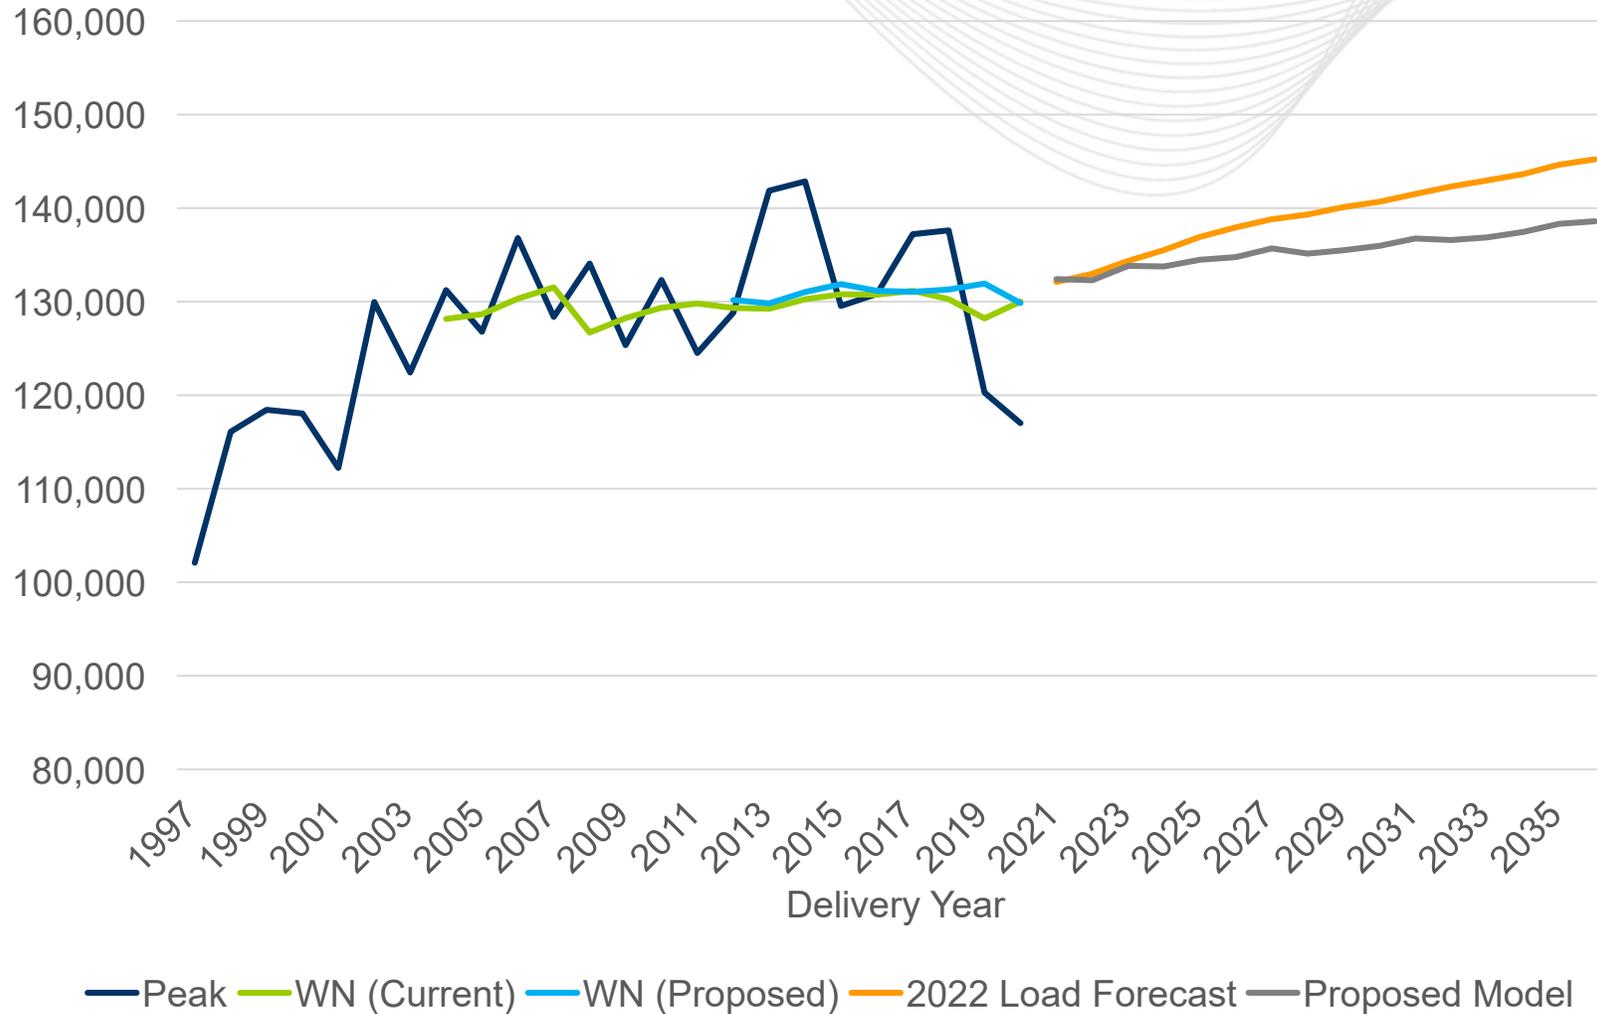

- Exclusion of relatively hot years in 1995 and 1999 causes the 90th percentile to move lower.

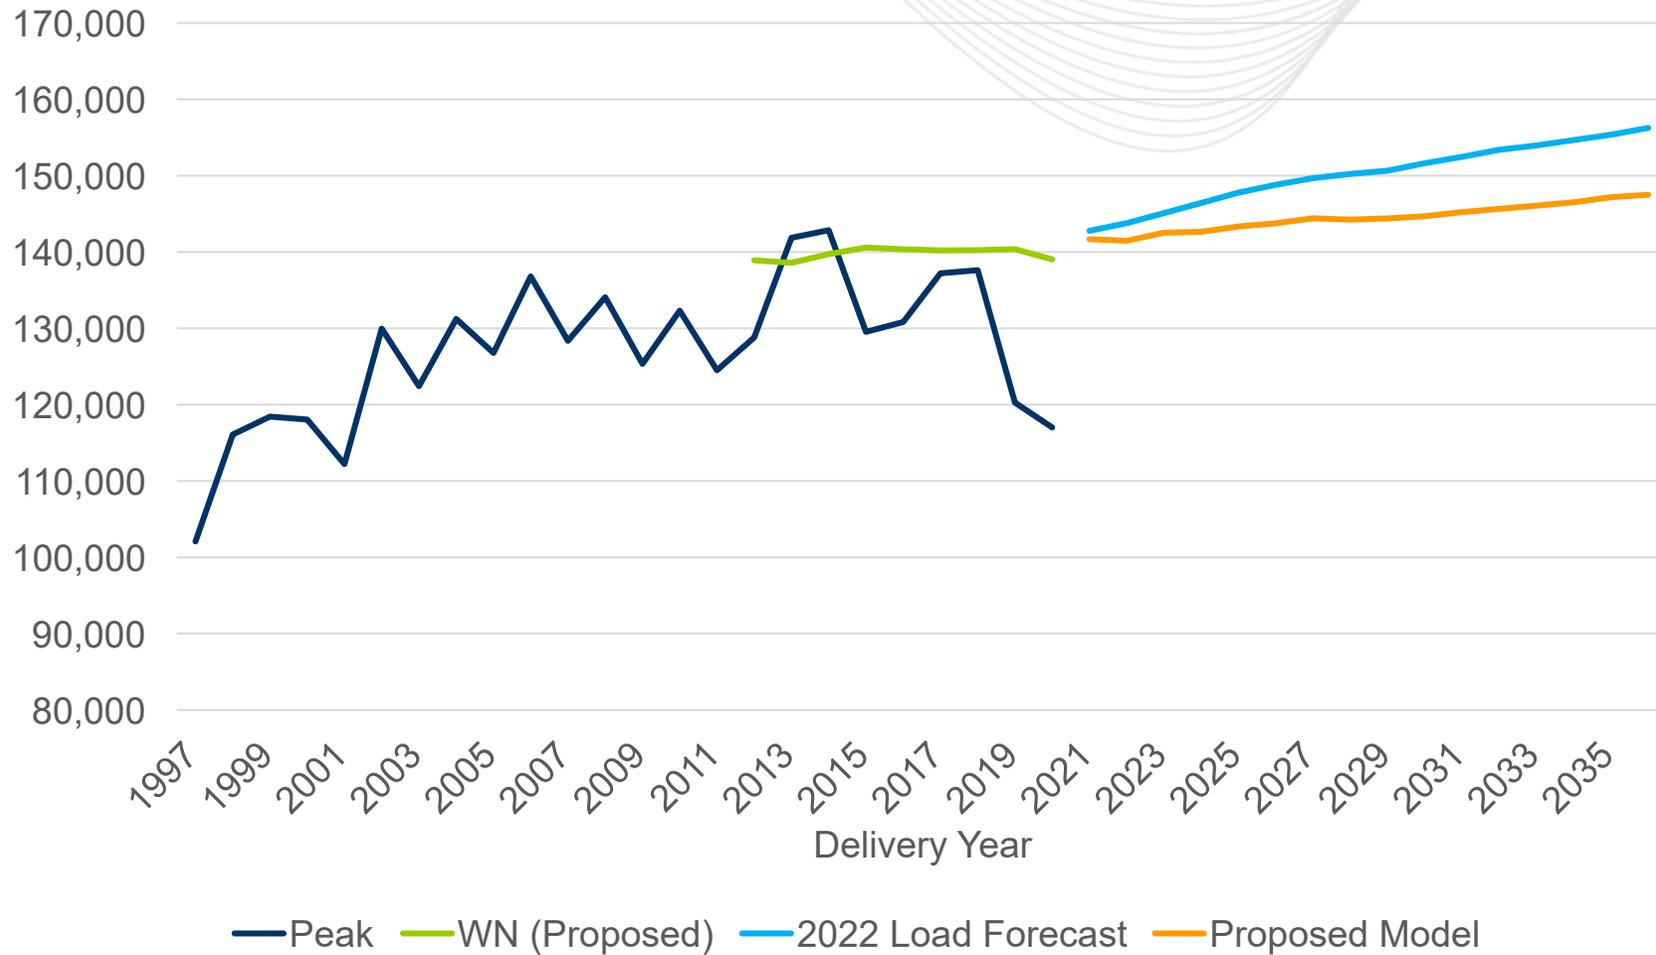

Decomposition of Summer Peak Load

- Base and HVAC load are generally flat
- Movement in growth mostly due to solar and adjs (data centers)

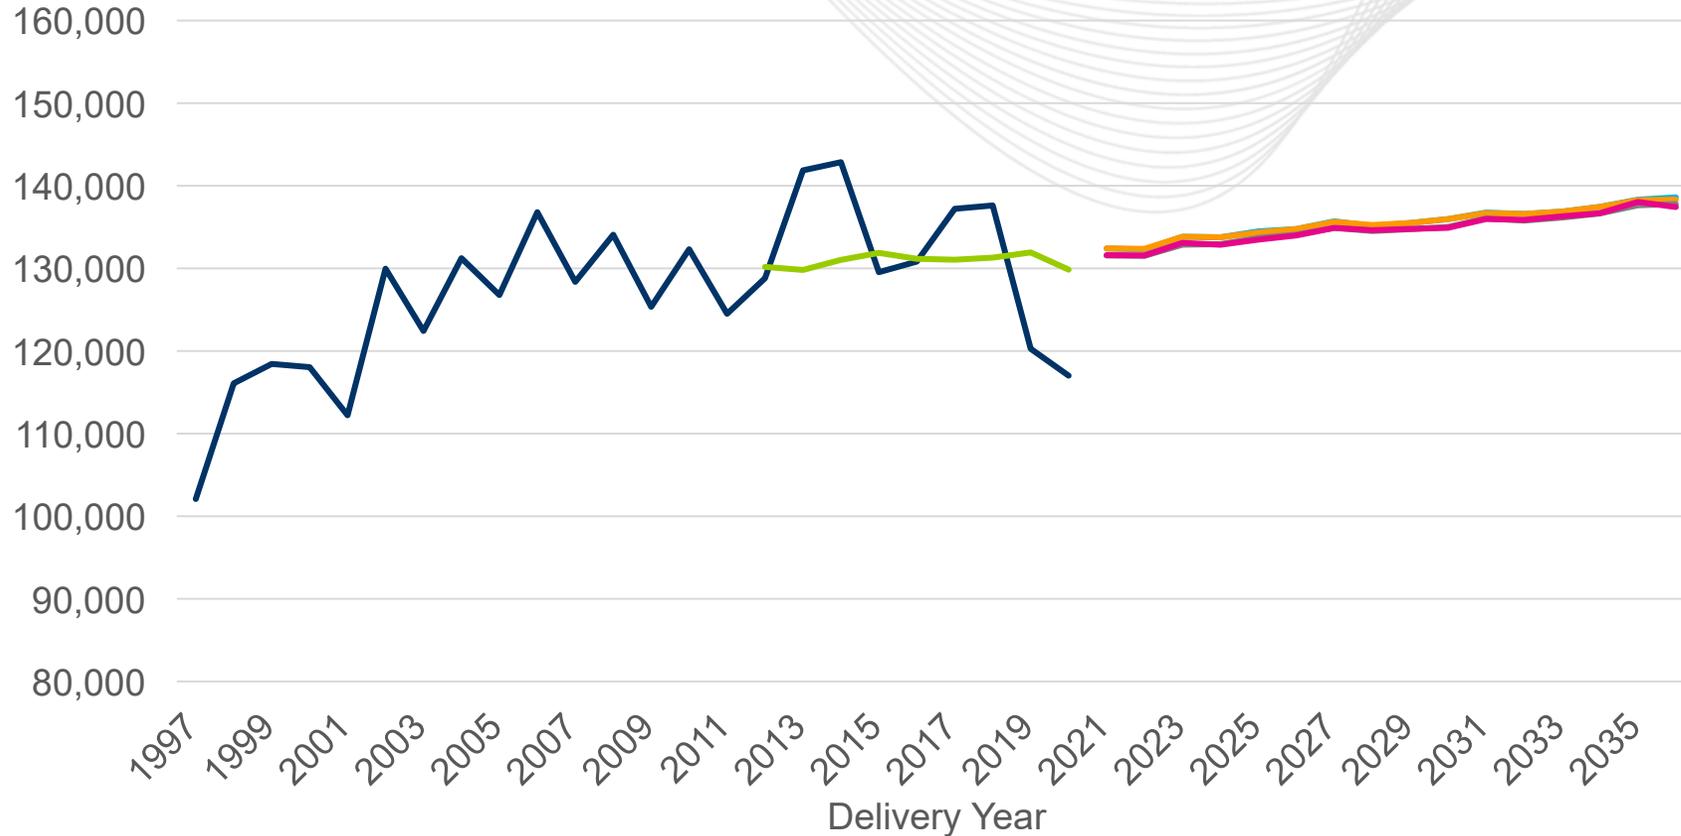

- Very similar starting point
- Slower 15-yr average annual growth rate
 - 0.3% vs 0.6% currently

- Lower starting point
- Slightly slower 15-yr growth

RTO 50/50 Winter Peak Forecast Impact of Weather Simulation Proposal

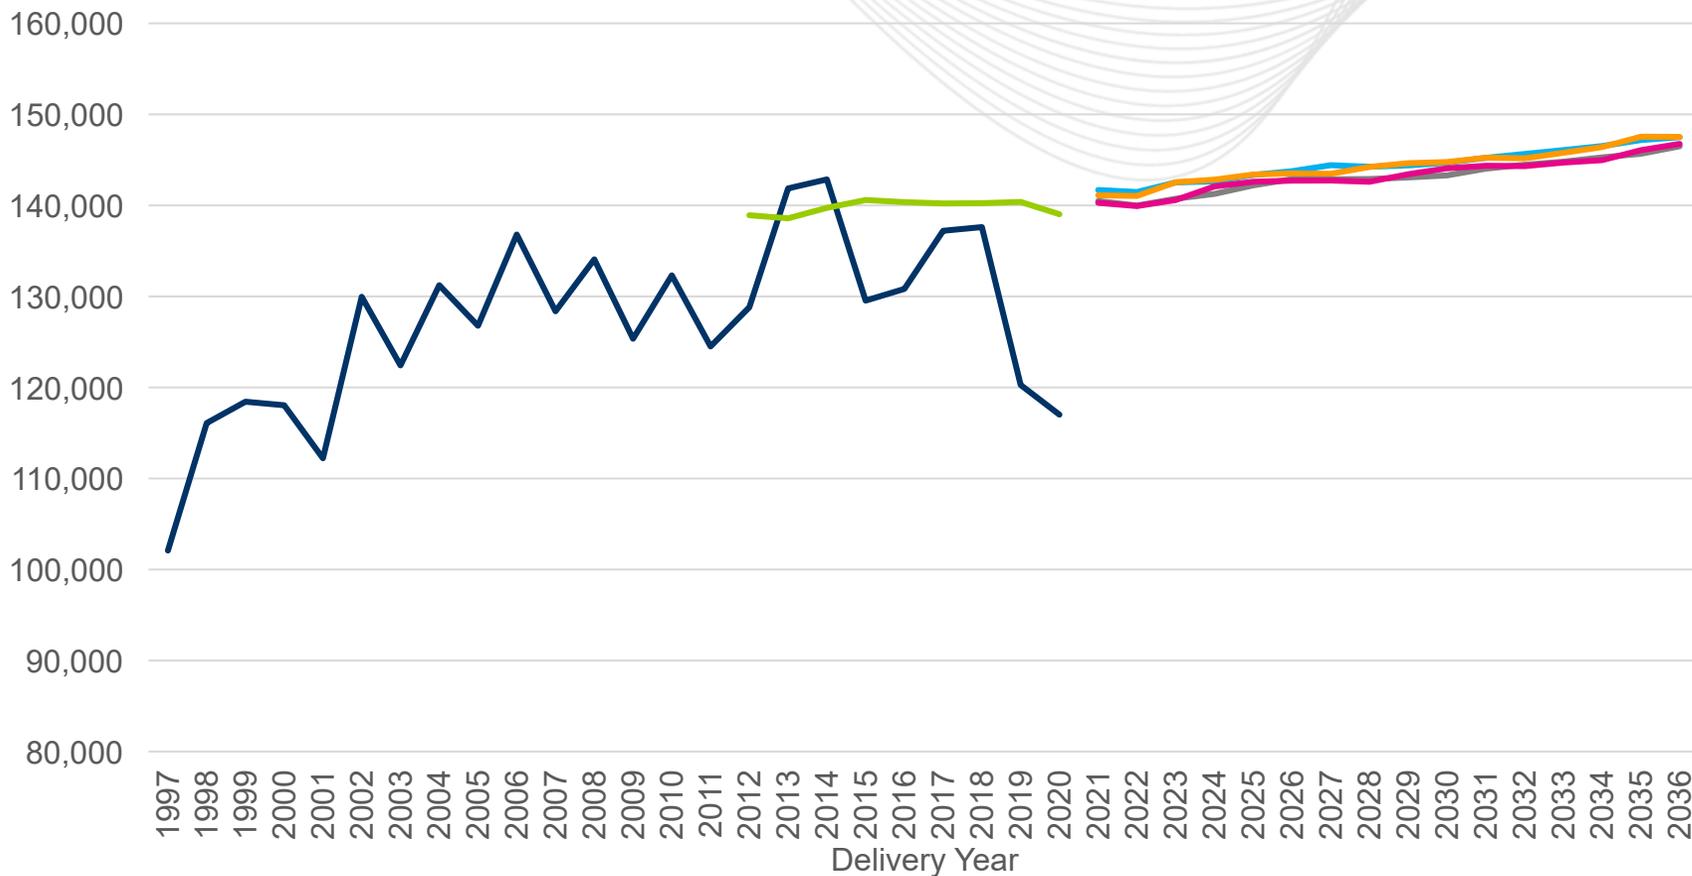

- Peak
- Proposed Model
- Shorten to 21 yr, Still 13 day
- WN (Proposed)
- Shorten to 7-day
- Shorten to 21 yr, and 7-day

- No significant impact to 50/50 forecast from changing the weather simulation

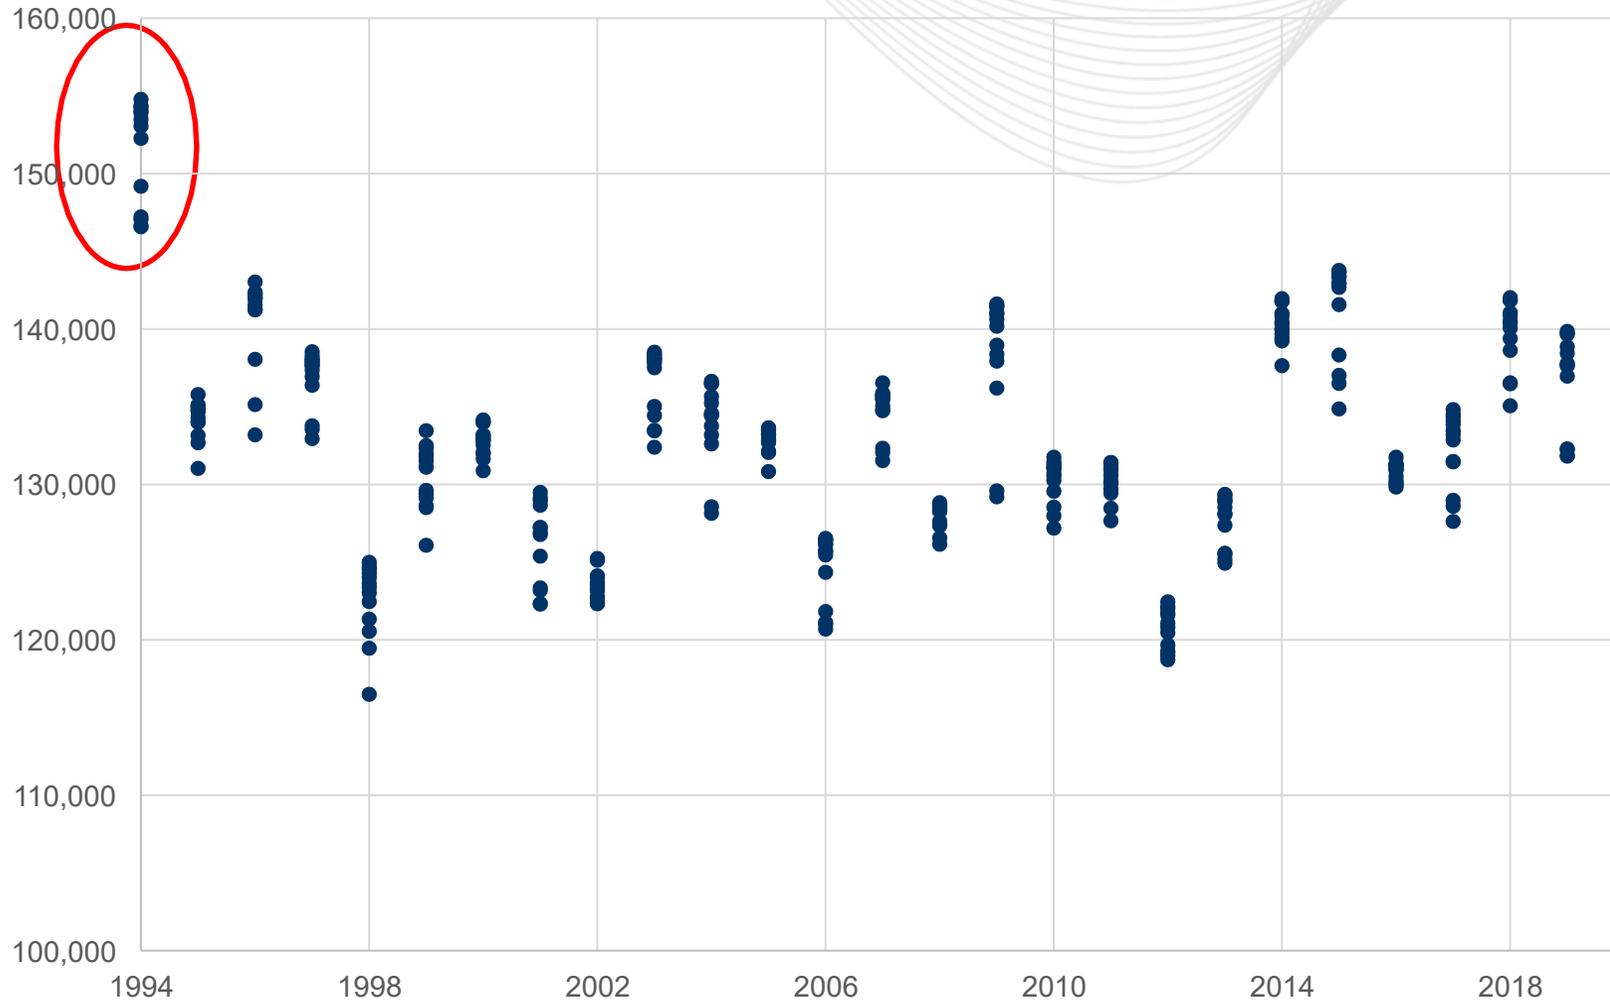

RTO 90/10 Winter Peak Forecast Impact of Weather Simulation Proposal

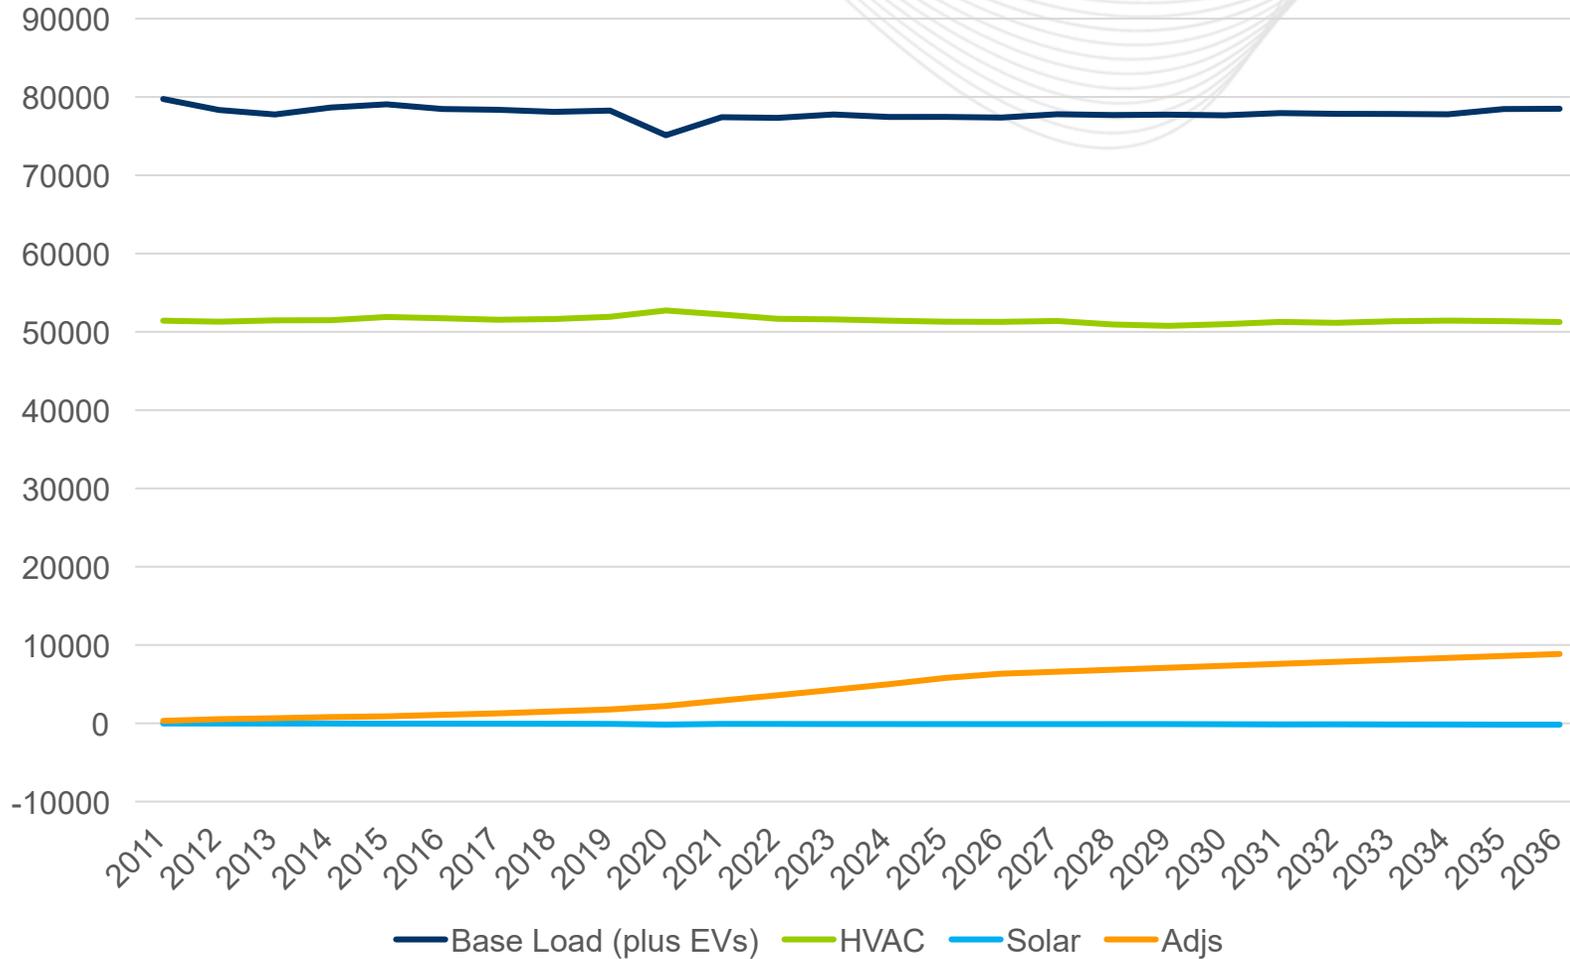

- Relatively small negative impact (~1%)

Winter Coincident Peak Distribution by Weather Year

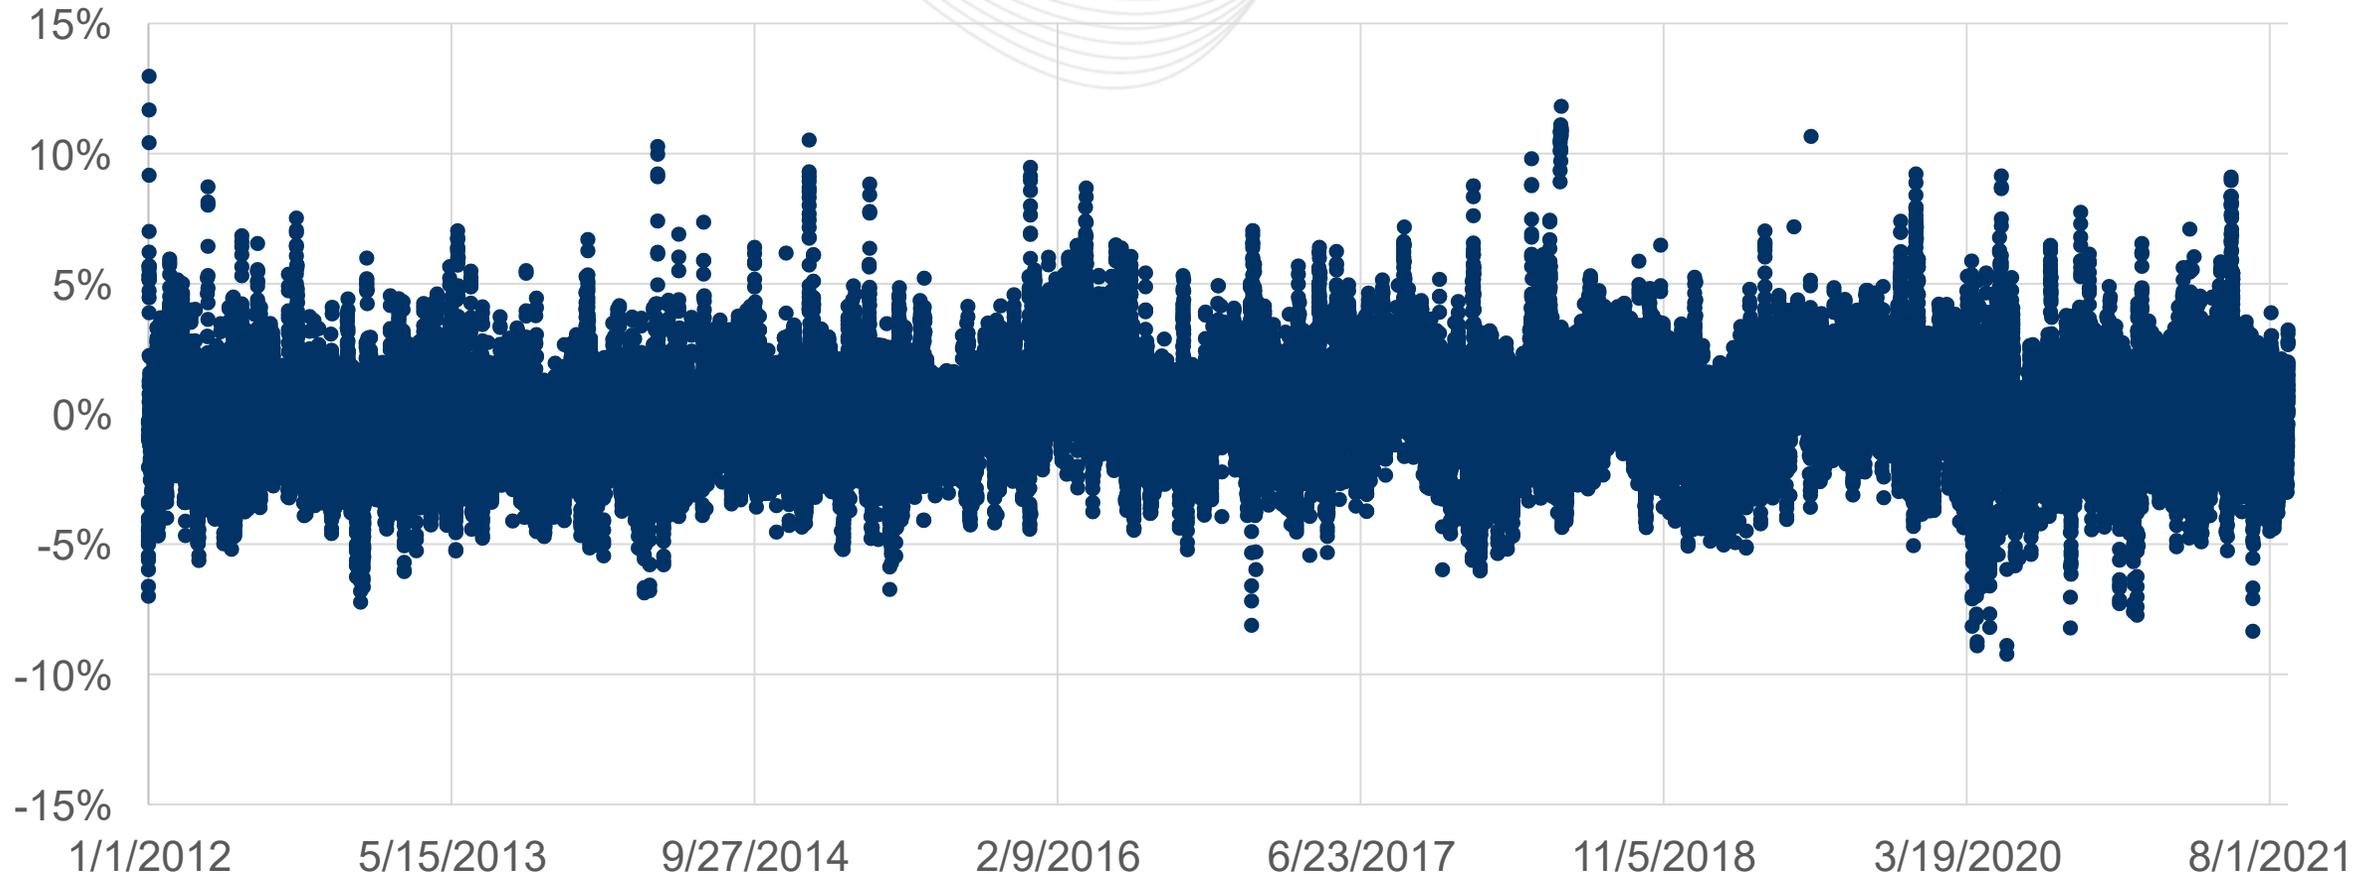

- Exclusion of 1994 winter would not have significant impact on 90th percentile, but would narrow the distribution.

Decomposition of Winter Peak Load

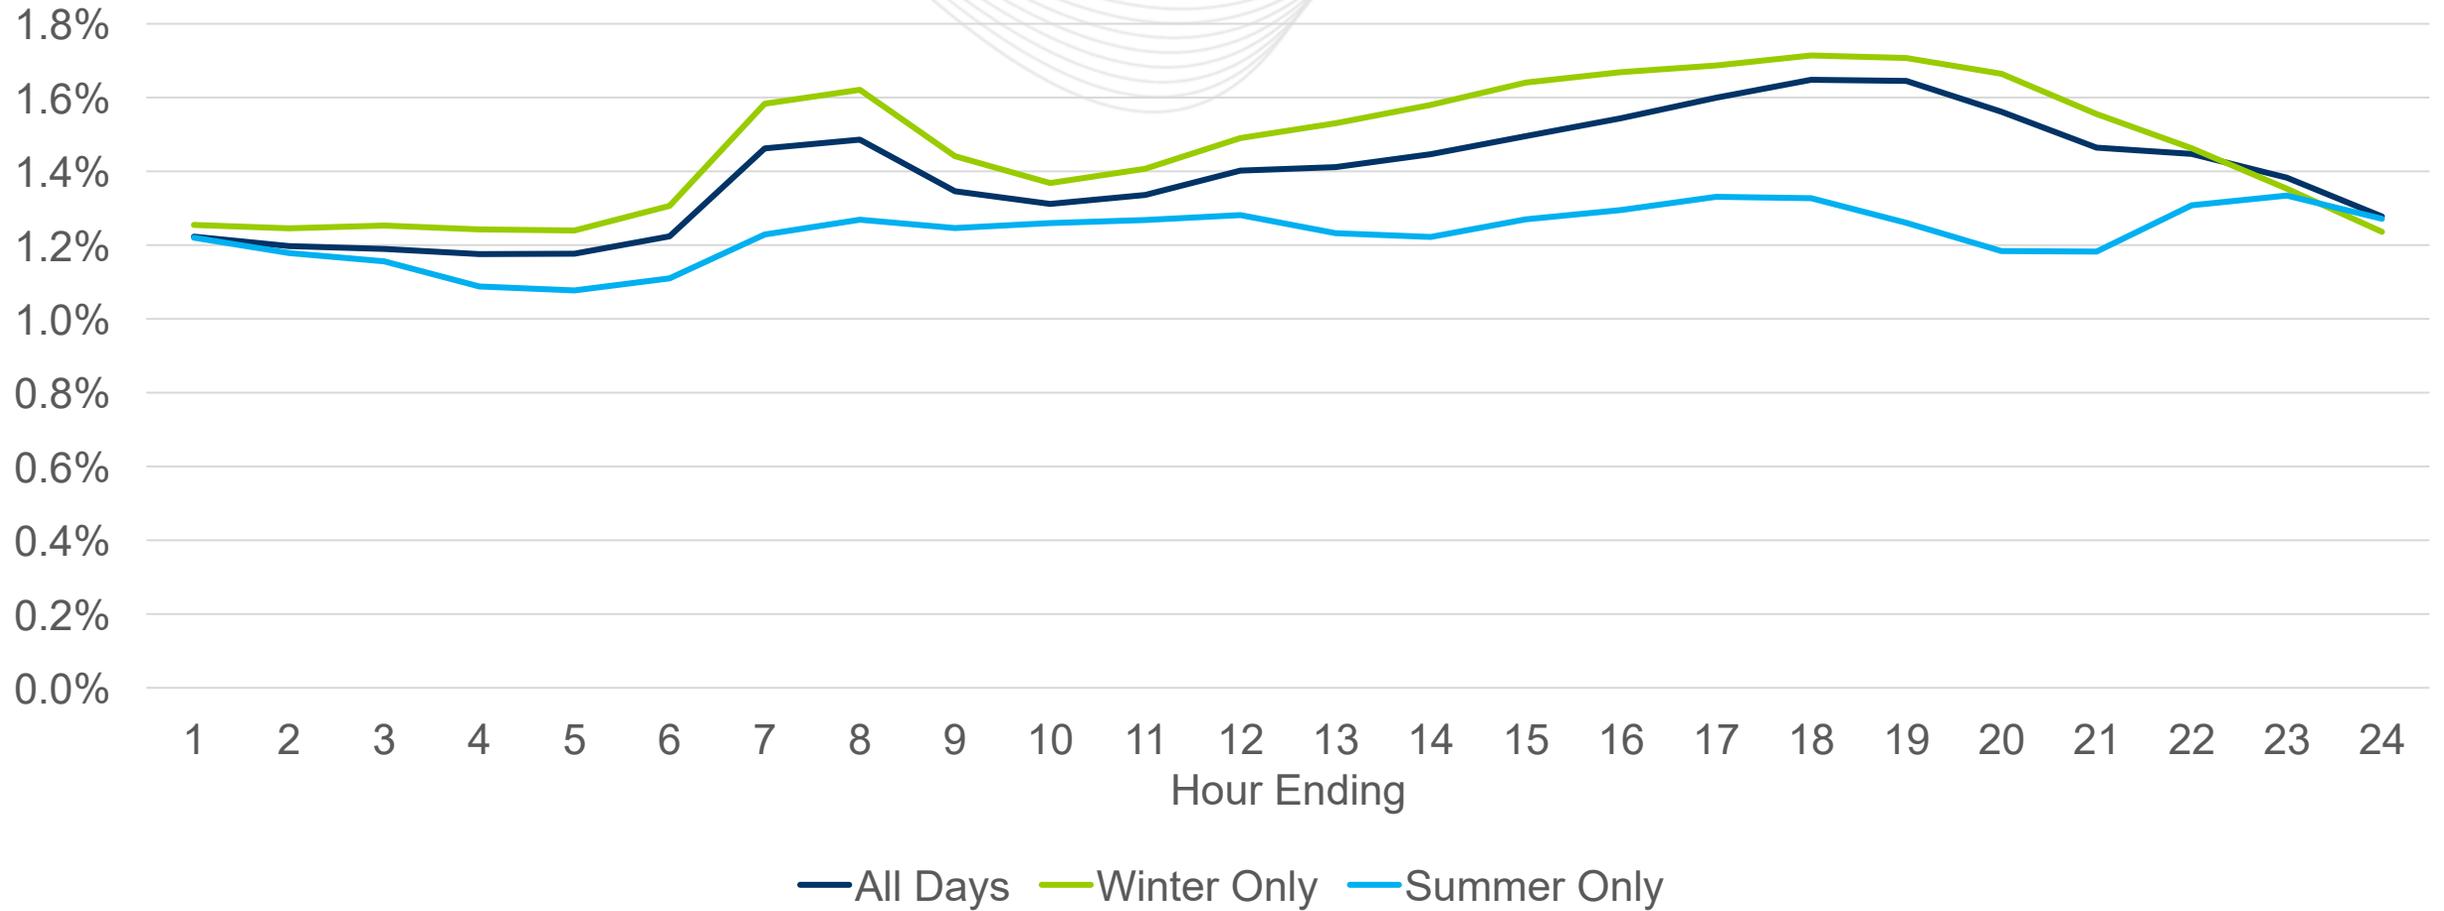

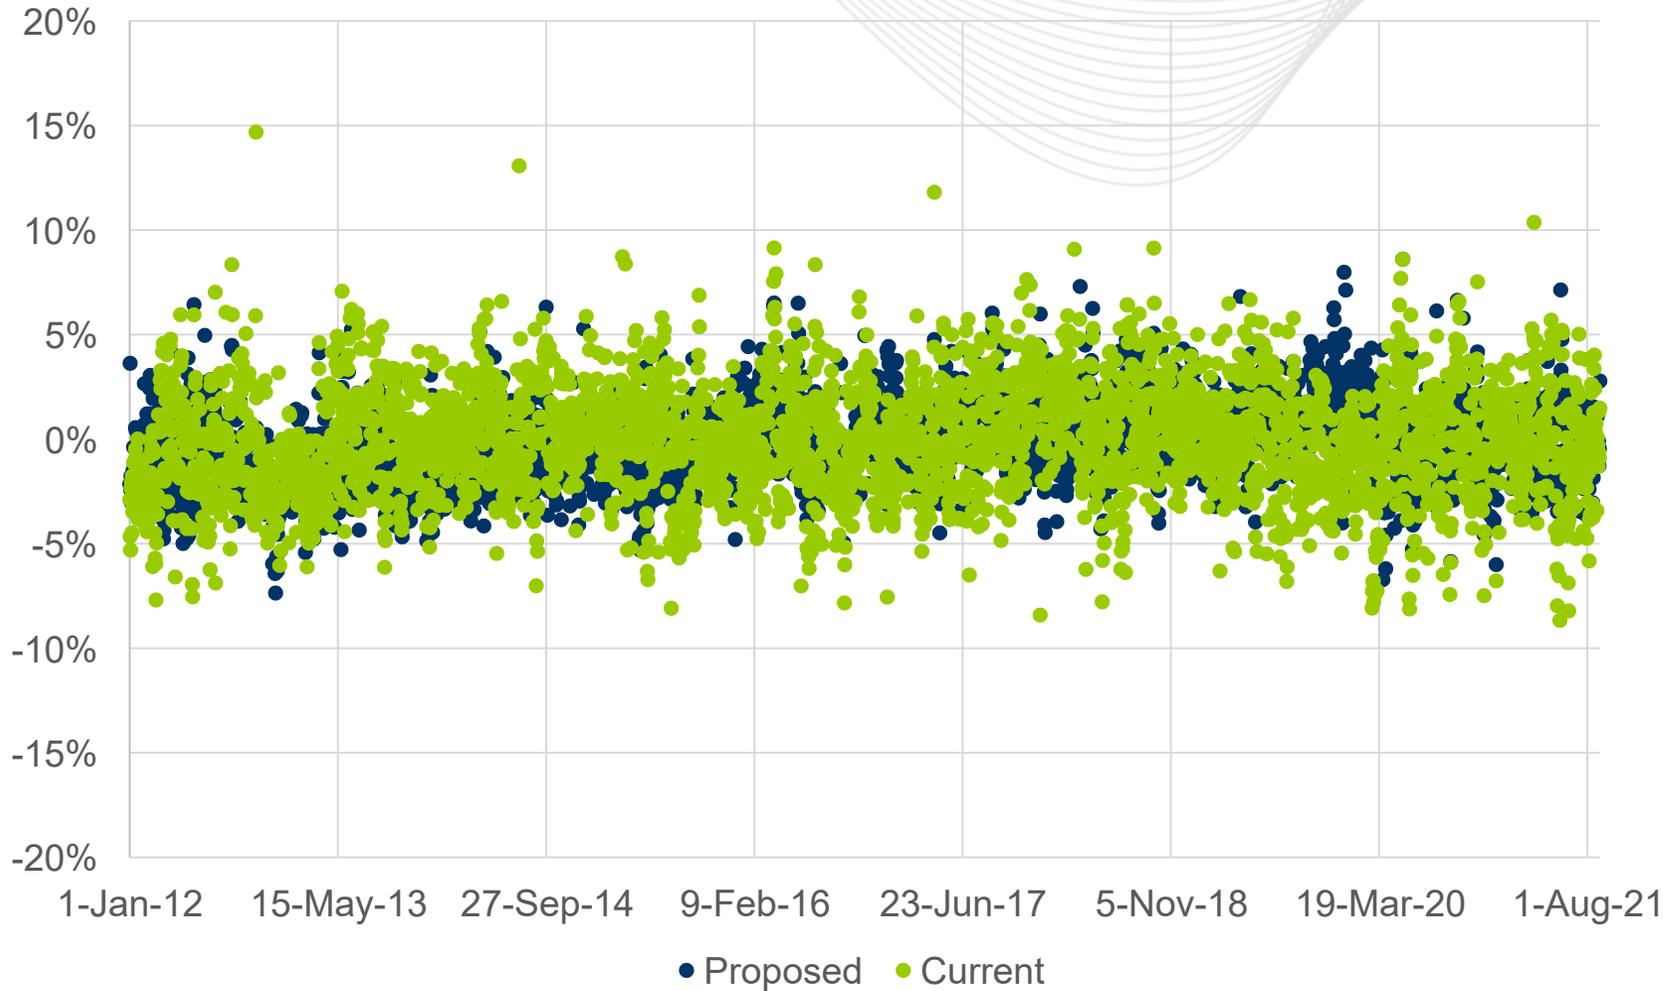

- Base and HVAC load are generally flat
- Movement in growth mostly due to adjs (data centers)

Hourly Residuals (%)

Mean Absolute Percent Error

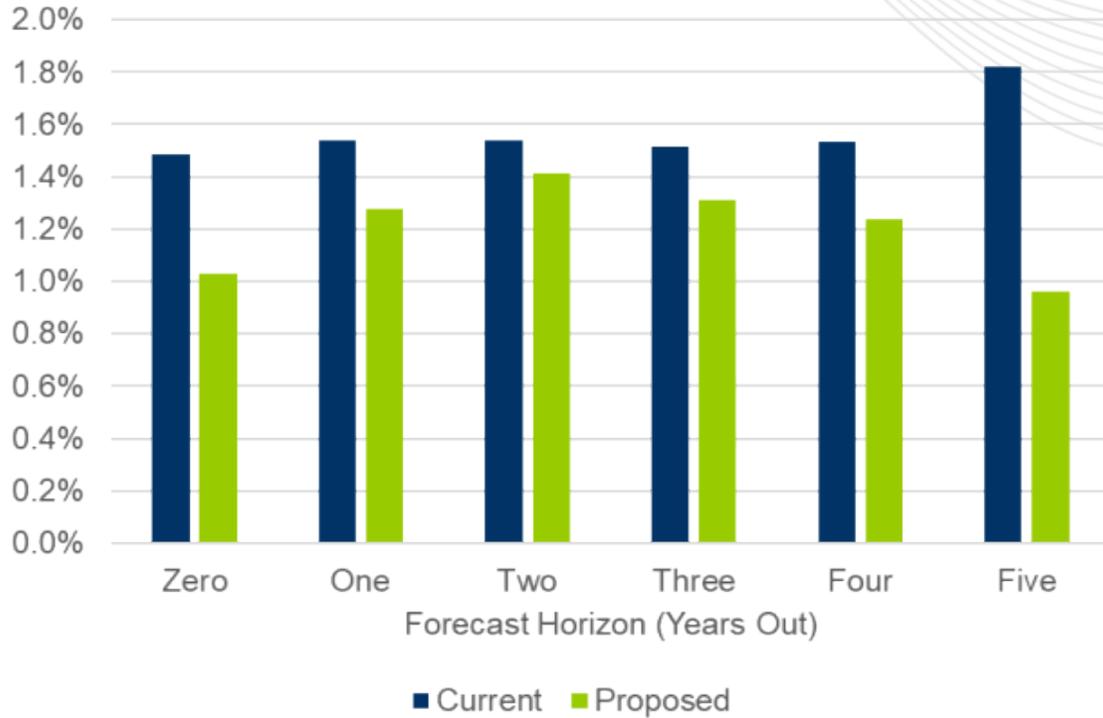

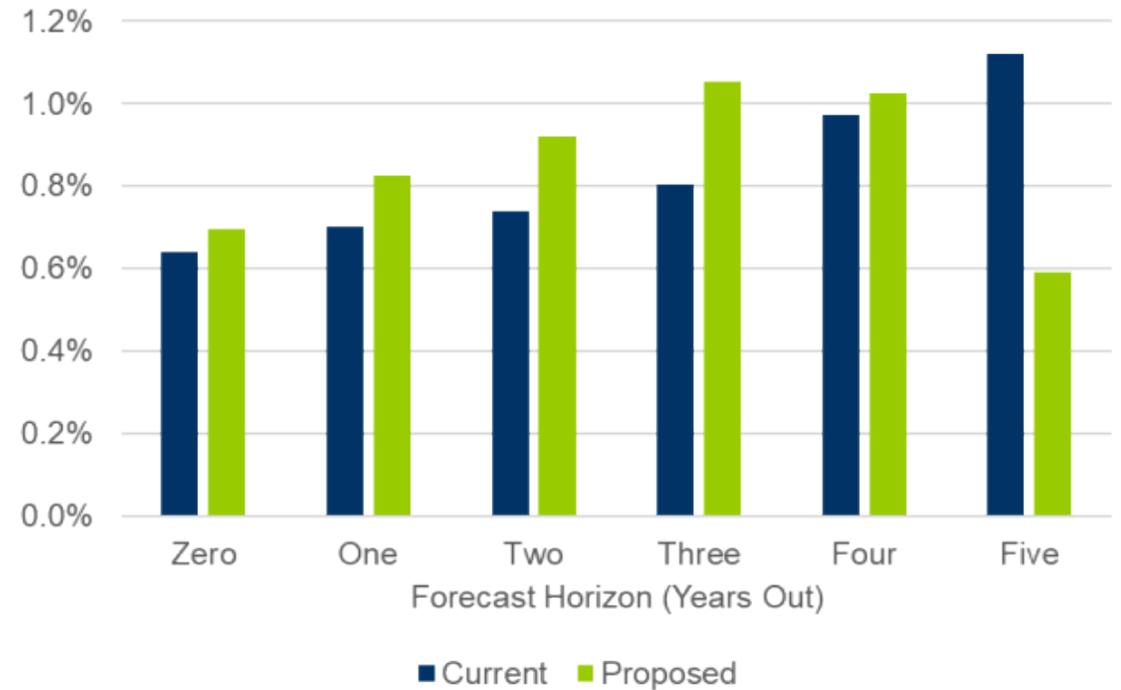

Mean Absolute Percent Error

- Current: 2.2%
- Proposed: 1.5%

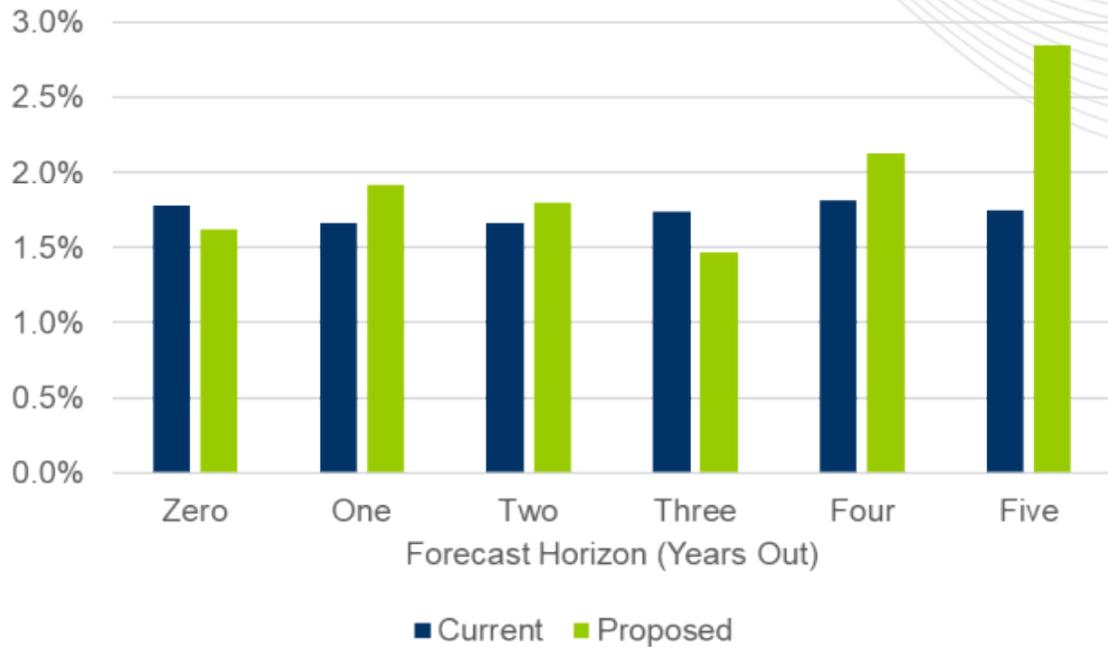

Summer MAPE on 10 CPs

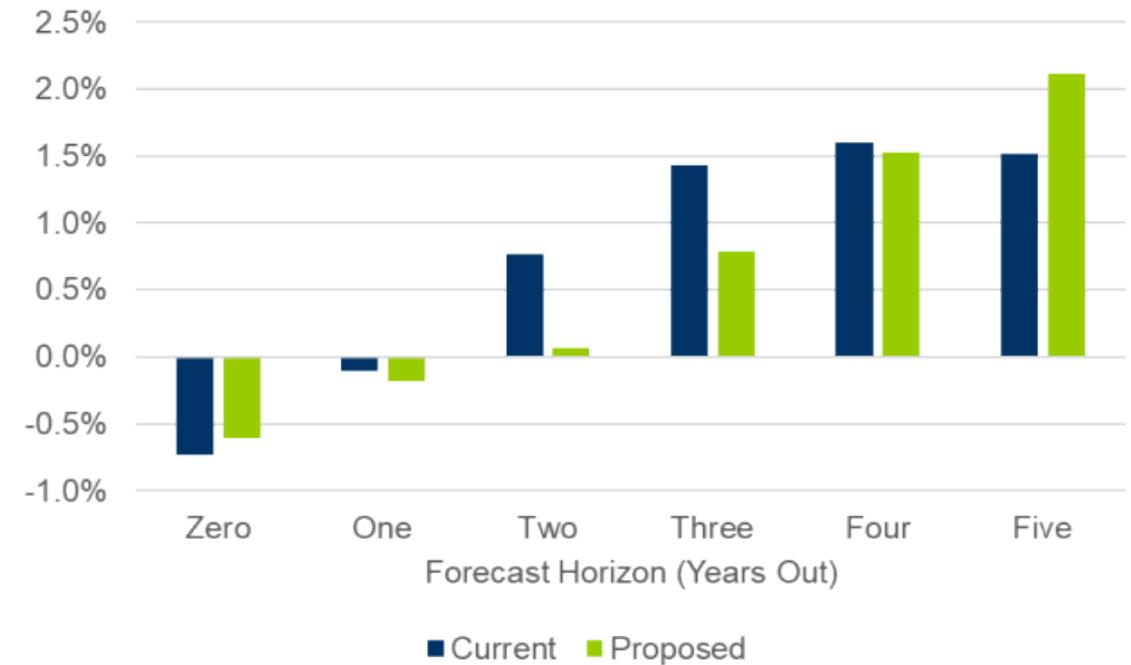

Summer MPE on 10 CPs

Winter MAPE on 10 CPs

Winter MPE on 10 CPs

- Seeking Stakeholder Feedback

- PJM Plan
 1. Use monthly sector models to construct driver variables
 2. Use hourly load models
 3. Consider new technologies through hourly shapes
 4. Continue with current historical weather simulation period to capture the range of potential weather events the RTO may face. Still considering whether to shorten to a 7-day rotation, but that decision has negligible impact on results.

- PJM is working on updating model inputs (load, end-use, economics, BtM solar & batteries, EVs, etc)
- Will present findings at November LAS (11/29) and December PC (12/6)
- Load Forecast Report will be published late December with Load Forecast Supplement to follow.
