Status Quo RPM and Reliability Backstop

www.pjm.com | Public PJM © 2025

RPM Impacts if Resource Inadequate

The Reliability Pricing Model (RPM) is the PJM resource adequacy construct that seeks to commit adequate Capacity Resources to provide reliable service to loads within the PJM Region

- RTO Supply is the accredited supply (ELCC) cleared in the RPM Auction for a future delivery year. Includes Internal and external (pseudo-tie) capacity and Demand Response.
- Reliability Requirement is used as basis to secure necessary future supply and is set to maintain a loss of load expectation (LOLE) on one occurrence in 10 years (1 in 10)

If the RPM RTO Supply < RPM RTO Reliability Requirement then PJM is forecasted to not meet its LOLE and the risk of manual load shed increases

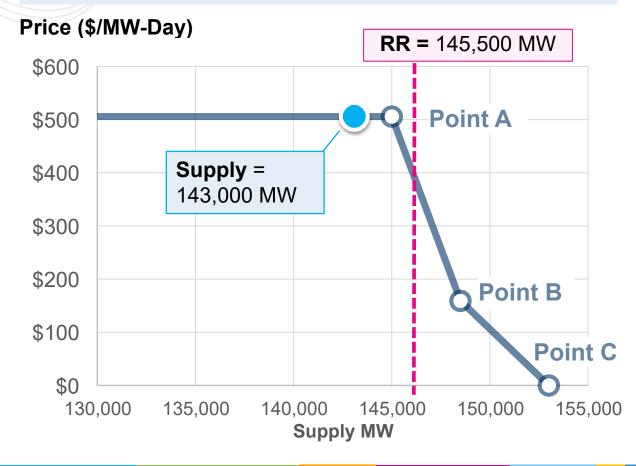

RPM Price impact if Supply < Reliability Requirement

Variable Resource Requirement (VRR)
Curve is a demand curve used in the clearing of the Base Residual Auction that defines the price for a given level of Capacity Resource commitment relative to the applicable Reliability Requirement.

In the example, the Supply < Reliability Requirement and also Point A and therefore the RPM price equals the maximum price (\$500 /MW-Day).

Point A establishes the upper limit for capacity prices derived from Cost of New Entry (CONE).

Example VRR Curve Supply < Reliability Requirement

RPM Reliability Backstop (Resource Adequacy) OATT Attachment DD section 16.4

Purpose

The Reliability Backstop provides a mechanism to resolve reliability criteria violations caused by: (a) lack of sufficient capacity committed through the Reliability Pricing Model Auctions; or (b) near-term transmission deliverability violations identified after the <u>Base Residual Auction</u> is conducted. These backstop mechanisms are intended to guarantee that sufficient generation, transmission and demand response solutions will be available to preserve system reliability. The backstop mechanisms are based on specific triggers that signal a need for a targeted solution to a reliability problem that was not resolved by the long-term commitment of Capacity Resources through Self-Supply or the Reliability Pricing Model Auctions.

Actions

Corrective actions may include adjusting the Cost of New Entry to the extent determined necessary by such investigation, or addressing other barriers to entry identified by such investigation. No Reliability Backstop Auction will be conducted to address such a shortfall unless it occurs in the Base Residual Auctions for three consecutive Delivery Years.

RPM Reliability Backstop (Resource Adequacy)

Trigger 1

If the total Unforced Capacity of all Capacity Resources committed through Self-Supply or the Base Residual Auctions for three consecutive Delivery Years, equates to an installed reserve margin that is more than one percentage point lower than the approved PJM Region Installed Reserve Margin, the Office of the Interconnection will declare a capacity shortage and make a filing with FERC for approval to conduct a Reliability Backstop Auction.

Trigger

If the total Unforced Capacity of all Base Load Generation Resources committed in a Base Residual Auction for a Delivery Year is less than the forecasted minimum hourly load calculated by the Office of the Interconnection for such Delivery Year, the Office of the Interconnection will investigate the cause of shortfall. If such a shortfall occurs in the Base Residual Auctions for three consecutive Delivery Years, the Office of the Interconnection shall declare a capacity shortage and make a filing with FERC for approval to conduct a Reliability Backstop Auction.

Reliability Backstop Auction

RPM Reliability Backstop Auction

Action

The Reliability Backstop Auction shall obtain commitments of **additional** Generation Capacity Resources (or, as applicable, additional Base Load Generation Resources) for a term of up to fifteen (15) Delivery Years. If a Reliability Backstop Auction is required, the offer period for such auction shall commence no later than four months after the Base Residual Auction in which the third consecutive Capacity Resource shortfall occurs. The offer period will be open for six (6) months. PJM Settlement shall be the Counterparty to the capacity transaction resulting from committed Capacity Resources clearing the Reliability Backstop Auction.

Sell Offers

Sell Offers shall include the following:

- 1. Minimum price in \$/MW-day required by the Capacity Market Seller to provide **additional** Unforced Capacity from a Generation Capacity Resource (or from a Base Load Generation Resource)
- 2. The megawatts of Unforced Capacity to be provided by such resource
- 3. The specific location of the proposed plant;
- 4. All information required from a Generation Interconnection Customer by Tariff, Part IV and the PJM Manuals;
- 5. General plant technical specifications, as specified in the PJM Manuals;
- 6. The term of cost recovery ("Backstop Period") requested, not to exceed 15 years
- The first full Delivery Year for which such resource shall be available, which shall also be the first year of the Backstop Period.

Status Quo - Operations Manual Load Dump Procedures

www.pjm.com | Public PJM © 2025

Scenarios leading to potential Load Dump

- RTO wide capacity shortage
- IROL exceedance indicating a large area capacity shortage and potential voltage collapse
- Local area transmission cascade/system collapse

PJM Capacity Alerts, Warnings and Actions

Alerts

Issued in advance of operating day/period

- Unit Startup Notification Alert
- Maximum Generation Emergency / Load Management Alert
- Primary Reserve Alert
- Voltage Reduction Alert

Warnings

Issued real-time typically, preceding Action

- Primary Reserve Warning
- Voltage Reduction Warning & Reduction of Non-Critical Plant Load
- Manual Load Dump Warning

Actions

Issued real-time requiring a response

- Pre-Emergency Load Management Reductions
- Emergency Load Management Reductions
- Maximum Generation Emergency
- Emergency Voluntary Energy Only Demand Response Reductions
- Deploy All Resources Action
- Curtailment of Non-Essential Building Load & Voltage Reduction
- Manual Load Dump

PJM recommends
Transmission Owner's initiate
public appeals for
conservation if any of these
procedures are issued.

PJM issues its own public appeals for conservation 12-15hrs in advance if a Voltage Reduction Alert is issued, or if a Voltage Reduction Action or Manual Load Dump Action have been initiated.

Manual Load Dump Action

Purpose

 Operating Instruction from PJM to shed firm load

Triggers

- Capacity: The PJM RTO cannot provide adequate capacity to meet the RTO load, and all other actions have been taken; or
- IROL* Exceedance: Critically overloaded transmission lines or equipment have exceeded limits and could lead to an uncontrolled system collapse (i.e. black out), and all other actions have been taken

PJM Actions

- Notify management, Members, DOE, FEMA, NERC, FERC, public/press release
- Estimate the Control Zone(s) and MW amount of load to be dumped <u>at</u> the Zonal level; instructs appropriate members to dump load according to EMS calculations

OA Schedule 1, Section 1.7.11 that states that "...the Office of Interconnection may not order a manual load dump in a Control Zone solely to address capacity deficiencies in another Control Zone."

Member Actions

- Notify management and applicable others
- Shed amount of load equal to, or more than, PJM's request, and maintain that load relief until cancelled by PJM
 - Load is shed based on TO customer prioritization
- Report the amount of load curtailed / restored as appropriate

*IROL – Interconnection Reliability Operating Limit as defined in Manual 37

- The PJM EMS calculates the Energy Position for each Zone by evaluating the real time generation output and the import/export schedules vs real time load
- The PJM EMS then compares this real time Energy Position to the cleared Capacity Position from the RPM auction to determine the Zone Position
 - ➤ NOTE: A zone may have more generation than load and still be short

Manual Load Dump Allocation - PJM Mid-Atlantic Region

If Mid-Atlantic region is deemed "short" in the EMS Load Dump Allocation calculations, total load shed must be further broken down by the Transmission Owners using the Manual Load Dump Allocation Tables from Manual M-13, Attachment E (shown above)

www.pjm.com | Public PJM © 2025

Transmission System Reliability: IROL Load Dump

 Transmission system reliability may necessitate the implementation of a Manual Load Dump Action to mitigate an IROL exceedance.

- PJM determines the MW relief needed
- Transmission Owners utilize the factors in the table to determine the Load Dump obligation

The following table is used for Transmission Owners and DPs to shed load in their zones to mitigate an IROL as described in Section 5.5:

| IROL Facility | East | Central | 5004/05 | West | AP-South | BED-BLA | AEP-DOM | CE-East | Cleveland | |

Transmission System Reliability: Local Area Load Shed

- Load shed may be initiated at the local level for any of the following:
 - Actual Overload: Actual flows exceeding Emergency Ratings (directive to shed load issued consistent with the time basis for the rating (i.e. 4hr, 2hr, 15 minute)
 - Cascade Analysis: Post contingency overload exceeding 115% of the Load Dump rating and analysis indicates an unbounded cascade (i.e. local area black out) may occur if the initial facility were to trip
- To determine the load shed MW and location, PJM issues a load distribution factor (dfax) report to the TO based on the actual or N-1 overload as dictated by system conditions, along with the pre or post contingency flow the TO must shed load to maintain
- The TO will use that report to surgically shed enough load to mitigate the emergency and avoid impacting critical loads (as determined by the TO), while also looking for opportunities to rotate

outages until system conditions permit restoration of load

Load shed for a local area issue is implemented based on the nodal load impacts and dfax, not at a TO zonal level

Status Quo RPM Obligations

www.pjm.com | Public PJM © 2025

RPM Locational Reliability Charge

- LSEs are charged for their Daily Unforced Capacity Obligation in a zone priced at applicable Final Zonal Capacity Price for the Delivery Year
- Charges are calculated daily and billed weekly

Daily Zonal UCAP Obligation MW

- Each zone with RPM load receives a share of the RTO-procured UCAP based on its share of forecasted peak load
- LSEs receive share of Zonal UCAP based on EDC allocation

Final Zonal Capacity Price

Weighted average price of capacity in zone (weighted by UCAP cleared in auctions):

- Marginal value of system capacity
- Locational Price Adders, if any, for zones in constrained LDAs
- Any required adjustments (e.g. make-whole payments)

Determining UCAP Obligations in RPM

Zonal UCAP Obligation MW

Total RTO-procured UCAP MW across all RPM auctions for the Delivery Year is allocated to each zone based on its share of forecasted peak load

Example (for RPM load):

- RTO procured UCAP MW in RPM Auctions = 140,000 MW
- RTO forecasted peak load for Delivery Year = 150,000 MW
- Zone A forecasted peak load = 15,000 MW (10% of total)
- Zone A UCAP Obligation = 14,000 MW (140,000 MW * 10%)

LSE Share of Zonal UCAP Obligations

Zonal UCAP Obligation MW are allocated to customers and LSEs in the zone based on EDC-defined methodologies

- EDCs are responsible for allocating prior summer weather normalized peak load of zone to customers and determining obligation peak loads (typically based on 5 CPs)
 - THEO, PLC & NSPL Methodology Inventory
- EDCs are also responsible for uploading obligation peak load data into system for each LSE serving load in their zone
- Obligation peak loads are multiplied by zonal scaling factors and FPR to determine each LSE's Daily Zonal UCAP Obligation MW

Numerical Example of Capacity Payments for LSEs in Constrained LDA

Locational Reliability Charges for Zone A (constrained LDA):

- Total RTO Procured UCAP = 140,000 MW
- RTO Forecasted Peak Load = 150,000 MW
- Zone A Forecasted Peak Load = 15,000 MW (10% of total)
- Zone A UCAP Obligation = 14,000 MW
- Zone A Final Zonal Capacity Price = \$200/MW-day (constrained in RPM auctions)

Locational Reliability Charges for Zone A (\$/day) = \$2.8 million (14,000 MW * \$200/MW-day)

CTR Credits for Zone A:

- Zone A Internal Cleared MW = 10,000 MW
- Zone A CTR MW = 4,000 MW (14,000 MW 4,000 MW); Assume all CTR MW allocated to LSEs in zone
- CTR Credit Rate = \$50 (RTO clearing price of \$150, locational price adder for LDA of \$50)

Offsetting CTR Credits for Zone A (\$/day) = **\$200,000** (4,000 MW * \$50/MW-day)

Net Load Capacity Payments (\$/day) = \$2.6 million (Locational Reliability Charges net of CTR Credits)

• Effectively paying for internal cleared UCAP (10,000 MW) * constrained price (\$200) + imported UCAP (4,000) * RTO price (\$150)

Key Takeaway: Zonal capacity charges in constrained regions are based on Locational Reliability Charges and offsetting CTR Credits, representing the economic value of imported capacity to meet the zone's UCAP obligation.

Capacity Obligation Load Adjustment

- PJM's existing load forecast process allows an EDC or LSE to propose a Load Adjustment to improve forecast accuracy (see M19, attachment B)
 - Specifies zone/area where Load Adjustment is applied
 - All Load Adjustments incremental to embedded forecast are published in Table B-9 of the forecast report (<u>forecast webpage</u>)
 - Load Adjustments that modify Capacity Obligations for a zone/area are published on the webpage link above in a separate file (Load Adjustment breakdown for Capacity Obligation.xls)
- Load Adjustment process allows EDC to assign adjustment to a specific LSE's Capacity Obligations

RPM Zonal Capacity Obligation

Zonal Capacity Obligation Calculations

- Zonal Peak Load Scaling Factor: B=(C-D)/A
 - Adjusts OPL by forecast, excluding RPM Load Adjustments
- Final Zonal Scaling Factor: F=B*E
 - Includes forecast and OPL Scaling Factors
 - OPL Scaling Factor scaled procurement to reported values
- Final Zonal UCAP Obligation: G=(A*F*FPR)+(D*E*FPR)
 - Scaled Peak Load + Load Adjustments

Allocation prior and during the Delivery Year

1. Obligation Peak Load (OPL)

| | | Load | | | |
|------|------|-------------|------------|--------|-----------|
| | | Responsible | Allocation | Scaled | |
| Zone | Area | Party | MW | LA MW | Total OPL |
| Z | Α | Q | 100 | 0 | 100 |
| Z | В | Q | 120 | 20 | 140 |
| Z | С | R | 140 | 10 | 150 |
| Z | D | S | 150 | 0 | 150 |

2. Peak Load Summary (PLC)

| | | | | Scaling | |
|-----|------|------|-----|---------|----------|
| LSE | Area | Zone | MW | Factor | OPL MW |
| 1 | В | Z | 40 | 1.1667 | 46.66667 |
| 2 | В | Z | 40 | 1.1667 | 46.66667 |
| 3 | В | Z | 40 | 1.1667 | 46.66667 |
| | | | 120 | | 140 |

3. Daily UCAP Obligation

| | | | | Daily |
|-----|------|------|--------|------------|
| | | | | UCAP |
| LSE | Zone | Area | OPL | Obligation |
| 1 | Z | В | 46.667 | 42.90255 |
| 2 | Z | В | 46.667 | 42.90255 |
| 3 | Z | В | 46.667 | 42.90255 |

1. Obligation Peak Load

- New column in Capacity Exchange Scaled LA MW
- Located in Load & Obligations->Wholesale Area Load
- OPL associated with Load Adjustments assigned to zone/area
- Adjusted OPL=(LLAMW/Final Zonal Scaling Factor) + OPL
- 2. PLCs are entered by EDC prior to DY (and updated daily, as necessary) and Scaling Factor calculated for each zone/area
 - Scaling Factor = Total OPL/Upload MW
 - OPL MW = Upload MW * Scaling Factor
 - Captures impact of LA on OPL of specific zone/area through the Scaling Factor
 - EDC may allocate LA to specific LSE, otherwise LA is allocated pro-rata across all LSEs in zone/area (as shown in example)
- 3. Daily UCAP Obligation calculated from OPL in Step 2
 - Daily UCAP Obligation = OPL * FPR * RPM Zonal Scaling Factor

PJM-EDC-LSE-Large Load relationship

How does Load interconnect onto the PJM System? Typically a 5-year process

PJM does not have a Load interconnection process.

Retail customer (Large load) Not a PJM Member

Load interconnection request

This function is performed outside of PJM

Utility is the Electrical Distribution Company (EDC) or Load Serving Entity (LSE) **PJM Member**

> Local Utility/TO **Studies**

Local Load interconnection analysis performed by Transmission Owner (TO) and supplemental project submitted to PJM (Attachment M-3 process) if necessary.

This function is performed outside of PJM.

PJM Planning includes submitted large loads in the load forecast and Regional Transmission **Expansion Process** (RTEP). Load included in RPM.

PJM Role

Interconnection "do no harm study" performed by PJM only for supplemental transmission projects submitted by TO.

Local Utility coordinates with load and TO for when load can interconnect.

Go-Live

Load interconnects after necessary transmission upgrades complete or allowed by TO

Electric Distribution Companies (EDCs) and Load Serving Entities (LSEs) are encouraged to provide PJM with information about large changes that may not be captured in the forecast process.

The Process

Manual 19:

Attachment B

Provides guidelines to ensure that any adjustments made to PJM's load forecast model are properly identified, estimated, and reviewed prior to incorporation into the forecast.

Large Load Adjustments Timeline 2026 Load Forecast

Official request sent July 1st to Planning Committee and Load Analysis Subcommittee

July

PJM requests information on potential load adjustments

<u>Early</u> <u>September</u>

PJM receives information on load adjustments and begins evaluation
September 5

<u>Mid</u> September

EDC/LSEs present on load adjustments to Load Analysis Subcommittee September 16

October/

November
PJM continues
evaluation and
presents

Appendix A Cascade Analysis Overview Operations

www.pjm.com | Public 9JM © 2025

NERC Standard PRC-023 R1.2 and R1.11

 Transmission line relays and transformer overload protection relays are set so they do not operate at or below 115% of the facility's highest emergency rating

PJM's highest rating for facilities is the **Load Dump** rating

- PJM will perform the following analysis for any facility that reaches or exceeds 115% of its Load Dump limit
- Study the loss of the contingency element and the overloaded facility

Cascade Analysis Procedure

PCLLRW is issued after:

- All other means of transmission constraint control have been exhausted, or
- Until sufficient generation is on-line to control the constraint within designated limits and timelines

If post-contingency flow were to exceed the 15-minute Load Dump rating, the facility may trip before actions can be taken to reduce the flow within limits

To prepare for this potential N-2 (initial contingency plus the overloaded facility) and prevent a cascade:

 PJM will perform up to an N-5 on facilities over 115% of their 15minute Load Dump rating

Cascade Analysis Procedure

If the study results indicate that:

- No additional facilities will be overloaded over 115% of their Load Dump limit:
 - This is a localized event, and no additional pre-contingency actions will be taken
- Additional facility(s) over 115% of its Load Dump rating, the operator will continue the analysis to also trip the additional circuits:
 - Analysis will be performed, tripping a maximum of 5 facilities
- Either a non-converged case, or continues to show facilities exceeding 115% of their Load Dump limits:
 - This will be considered a potential cascade situation
 - The PJM operator will review the results with the Transmission Owner and direct pre-contingency Load Shed.
